*Quaestiones Entomologicae*  
26: 383–557 1990

ABSTRACT

Each of the 26 species of the world fauna of *Dytiscus* Linnaeus is keyed, defined, characterized and illustrated. Arrangement of *Dytiscus* into subgenera is unwarranted based on the phylogenetic analysis presented. Taxonomic changes include recognition of *D. carolinus* Aubé 1838, formerly confused with *D. fasciventris* Say 1824; *D. validus* Régimbart 1899 is placed as a junior subjective synonym of *D. sharpi* Wehncke 1875; use of *D. czerskii* Zaitsev 1953 at subspecific rank for eastern Palearctic specimens of *D. marginalis* Linnaeus 1758 (western Palearctic specimens); *D. marginalis* is not found in the Nearctic region; arrangement of *D. lapponicus* Gyllenhal 1808 into two subspecies, the nominate, widespread Palearctic form, and *D. lapponicus* *disjunctus* Camerano 1880 from the Italian Alps; and placement of *D. piceatus* Sharp 1882 as a junior subjective synonym of *D. latro* Sharp 1882 (page priority); *D. mutinensis* var. *striatus* Leblanc 1982 is placed as a junior subjective synonym of *D. dimidiatus* Bergsträsser 1778. The name *D. albionicus* Motschulsky 1859 is transferred from a junior synonym of *D. circumcinctus* Ahrens 1811 to a junior synonym of *D. marginicollis* LeConte 1845. Lectotype designations are provided for the following: *D. sharpi* Wehncke 1875 (male in MNHN, labelled: Japonia); *D. validus* Régimbart 1899 (male in MNHN, labeled: Nagahama); *D. pisanus* Castelnau 1835 (male in BMNH, labelled: Italia); *D. submarginalis* Stephens 1828 (= *D. marginalis* L.) (male in BMNH, without locality data); *D. angustatus* Stephens 1826 (= *D. circumcinctus* Ahrens 1811) (male in BMNH, without locality data); *D. parvulus* Motschulsky 1852 (= *D. alaskanus* J. Balfour-Browne 1944) (male in UMHF, labelled: Kadjak); and *D. dauricus* Gebler 1832 (male in MNHN, labelled Sib.or. 62). Holotypes were studied of *D. marginicollis* LeConte 1851 (MCZC), *D. hatchi* Wallis 1950 (CNIC), *D. sublimbatus* LeConte 1857 (= *D. cordieri* Aubé 1838) (MCZC), *D. pisanus* var. *nonsulcatus* Zimmermann 1919 (ZSBS), *D. persicus* Wehncke 1876 (MNHN), *D. latro* Sharp 1882 (BMNH), *D. piceatus* Sharp 1882 (= *D. latro* Sharp 1882) (BMNH), *D. stadleri* Gschwendtner 1938 (= *D. latro* Sharp 1882) (ZSBS), *D. sinensis* Feng 1935 (USNM) and *D. thianshanicus* Gschwendtner 1923 (OLML). In addition the name *Dytiscus* *distantus* Feng 1937 (Type locality - Manchuria) is *incertae sedis*.

Treatment of each taxon includes, when appropriate: synonymic list with information about type locality and label information from types examined, derivation of epithet; notes about type material; diagnostic combination; description in tabular form; taxonomic notes; discussion of variation; brief discussion of natural history; general description of distribution as well as map

of localities; chorological and phylogenetic relationships. In addition line drawings are provided of: dorsal aspects of adults; color pattern of pterothoracic and abdominal sterna; metacoxal processes; and trochanters. Views of dorsal, ventral and lateral aspect of the median lobe of genitalia of adult males are represented by scanning electron micrographs.

A preliminary reconstructed phylogeny shows that the sister group of Holarctic *Dytiscus* is the Australian genus *Hyderodes* Hope; these two genera comprise the tribe Dytiscini. The most plesiomorphic species of *Dytiscus* is the Nearctic species, *D. verticalis* Say, 1823, and it is assigned to its own species-group; the next species-group to diverge is represented by a clade of four Nearctic species; female specimens of these two clades have non-sulcate elytra. The remaining 21 species are arranged in four species-groups. Three of these species-groups occur in both Nearctic and Palearctic regions; the majority of females in these species-groups have sulcate elytra.

## INTRODUCTION

The genus *Dytiscus* is one of the 25 genera originally recognized as comprising the Coleoptera by Linnaeus (1758:342). The Linnaean definition of *Dytiscus* was based primarily on natatory setae on the posterior legs, and as such it contained beetles now assigned to Hydrophiloidea and Dryopoidea as well as Dytiscoidea. Of the fifteen taxa assigned to *Dytiscus* by Linnaeus, only two (*D. latissimus* and *D. marginalis*) are accepted within the present definition of the genus, established by Erichson (1832).

The correct spelling and meaning of the generic name has engendered controversy. According to Blunck (1913:8) and J. Balfour-Browne (1960), Geoffroy (1762:185) was probably the first author to note that *Dytiscus* was an incorrect transliteration of the Greek word for 'diver'. Many authors subsequently used the emended "*Dyticus*" or "*Diticus*", although Schmiedlin (1786:239) suggested that Linnaeus' spelling may be derived from the word 'disci' referring to the form of the male protarsus of specimens of *Dytiscus*

(Blunck 1913:9). This would appear unlikely given the composition of the genus by Linnaeus. The present spelling of the generic name was established as valid in 1961 by Opinion 619, Bulletin of Zoological Nomenclature 18.

One hundred years have passed since the world fauna of *Dytiscus* was last treated taxonomically (Sharp 1882). Previous to this, the only comprehensive analysis of the burgeoning knowledge of the world fauna was by Aubé (1838). Both monographs included much new knowledge about adult Hydradeephaga in general, and about members of *Dytiscus* in particular. Many of the characters used in the present classification of these groups were presented first in these works. These books, in my opinion, represent two of the most outstanding studies of classification of Hydradeephaga. Quality and importance of such works is dependent upon two factors: ability of the author and quality and diversity of specimens available. The high degree of ability of both these workers is evident from, and has been tested by, the continuing importance of these publications. Almost as important are the collections with which these men worked. Aubé and Sharp had the advantage of extensive, worldwide collections accumulated within Europe during the 18th and 19th centuries.

Blunck (1913:2-30) discussed the early, including pre-Linnean, taxonomic history of *Dytiscus*. Blunck's treatment is exceptionally thorough and is invaluable as a source for, and interpretation of, the early treatises which include various species of *Dytiscus*, but perhaps more importantly, he has allowed entrance into philosophical and interpretive aspects of the work of these early systematists. This is particularly useful because of the nomenclatural problems such as those created by the treatment of dimorphic adult females (elytron either sulcate or non-sulcate). Perhaps no other feature of *Dytiscus* has led to the proliferation of names, long and sometimes heated discussions of nomenclature in the literature, as well as loss of time from more important taxonomic endeavours, as has that created by the occurrence of two states of female elytra. The two forms of any given European species were provided consistently with separate specific level epithets. Subsequent demonstration of the dimorphic nature of this variation has led to retention and demotion of these names to the level of variety and aberration. Use of such names in one taxon has precipitated creation of corresponding names in other taxa, which has in turn brought about debate of proper assignment of varietal names, concluding in further confusion and nomenclatural difficulties.

The Zoological Institute of Marburg, Germany must have been an exciting place for study of dytiscids during the late 19th and early 20th centuries. Professor E. Korschelt was in charge of a battery of students whose general project was intensive and careful investigations of all aspects of classification, natural history, structure, function, *etc.* of *Dytiscus*. This group concentrated on one of the larger, most commonly available species, *Dytiscus marginalis* L. Their collective efforts culminated in a magnificent two volume work of more than 1800 pages edited by Korschelt (1923, 1924). Some, but not all, chapters of this work were published elsewhere by the contributing authors. This work and subsequent contributions by both these and other workers must make *D. marginalis* at least one of the most studied members of Adephaga and possibly one of the most studied beetles.

Since Sharp's (1882) monograph, additional names and synonyms have been proposed, and many new distribution records acquired. Because of the amount of information available concerning various members of *Dytiscus*, even knowledgeable coleopterists have assumed that this genus was well understood taxonomically. However, those who have attempted to identify specimens of

*Dytiscus* to species (from areas outside Europe) discovered that this was difficult to accomplish. Reference to such recent works as Wallis (1950), Zaitsev (1953:341-354), Pederzani (1971) and Larson (1975:394-405) demonstrated that there was no lack of distinctive character states in external features and male genitalia, yet showed that type material of some species was inadequately understood and generally made it apparent that much still remained to be discovered about classification of the species of this genus. More specifically, they revealed that an adequate revision would have to be based on a world-wide study.

Achievement of the means to identify easily and accurately specimens of species is only the first step in gaining understanding of a genus. Additional steps which taxonomists ought to take are analyses of any further information that they have available concerning the members of the genus (i.e. holomorphological, chorological, paleontological and parasitological - Hennig 1966) and integration of this into an appreciation of evolutionary aspects of the taxon under study. Amount of the latter two types of information is severely limited for *Dytiscus*.

Part 1 of this revision offers means of identification of adults, information about type specimens, description of adult stage, a brief characterization of natural history and geographic distribution of species of *Dytiscus*. Subsequent parts of the revision will deal with immature stages and then these data will provide the basis for phylogenetic and zoogeographic analyses.

## MATERIAL AND METHODS

### Material

This revision is based on study of about 20,000 adult specimens of *Dytiscus*, either borrowed from museums or personally collected. The following alphabetically arranged codens represent collections from which specimens were borrowed or at which specimens were examined. Names of respective curators are also presented. In this list, private collections have the person's name placed first, after the coden. For institutional collections, the curator's name is placed last. My collection is included in the material denoted JBWM.

## Methods and Techniques

*Cleaning and dissection of specimens.*— Many specimens of *Dytiscus* are greasy and dirty, and, as such, they are not useful for detailed examination of structural features. Specimens were cleaned by placing them in a beaker of warm water to which was added a small amount of ammonia-enriched detergent. The beaker was placed on a hot plate adjusted to low heat for about 12 hours. After removal, specimens were rinsed with clean water and appendages positioned to avoid possibility of breakage.

Dissection of genitalia preceded the clean-water rinse. A number of techniques for extracting the sclerotized terminalia of adult *Dytiscus* were tried. The most effective method for male specimens is to grasp the relaxed beetle in one hand and to deflex the abdomen. An incision made between the third and fourth terga allows the base of the median lobe and parameres to be grasped with a pair of fine forceps. By pushing anteriorly and then pulling upward and posteriorly, the median lobe and parameres of most specimens can be extracted without damage and the remainder of the aedoeagus left in place. Removal of the male genital capsule by grasping the apex of the median lobe, parameres or associated structures is to be avoided because of the probability of damage. The median lobe is best separated from the parameres by placing two pairs of forceps into the basal space provided by the curvature of the median lobe and then gently pulling the forceps in opposite directions. This technique pulls the base of the

median lobe away from the bases of the parameres and allows for clean preparation with a minimum of damage.

Terminalia of adult female specimens were dissected in a different manner. Musculature around an ovipositor was cut with a lancet inserted through the abdominal apex and then the capsule pulled out with forceps. Because stylomere I, at rest, is flexed anteriorly over the top of the remainder of the capsule there is little possibility of damage using this technique. Preliminary analysis of shape of the apex of stylomere I (e.g. Pederzani [1971:221], Régil and Salgado [1984]) indicates that this feature may be taxonomically useful. However, the distinction among taxa is difficult to characterize and was not used in this study.

Portions of both male and female genitalic capsules removed from specimens were glued to cards placed on the pin of the specimens from which they were removed. Teneral or unsclerotized genitalia were placed in small, glycerine-filled vials and mounted on the specimen pin.

*Measurements.*— Adult specimens of *Dytiscus* were measured for total length (TL) and greatest width (GW) of the body. A ratio of these values (TL/GW) gives an index of body shape. Measurements were taken by means of a moveable stage Vernier scale to which a specimen holder was attached. By aligning a set of cross-hairs in the microscope eyepiece with an end of the beetle and then turning the knob on the stage micrometer until the other end of the specimen was lined up with the cross-hairs, the numerical value could be read from the scale on the stage micrometer.

An investigation of absolute size measurements of specimens of *Dytiscus* and its taxonomic value was initiated after noting discrepancies in overall size of specimens. For instance, Larson (1975:397) commented on the smaller mean TL of adult specimens of *D. harrisii* from Alberta and the Northwest Territories compared to specimens from Ontario and Wisconsin. I found a similar but less striking difference: average TL for 10 specimens from Alaska, Alberta, Northwest and Yukon Territories was 34.9 mm, compared to 36.8 mm for 10 specimens from Ontario. Three adult male specimens of *D. harrisii* which I collected by bottle traps near Old Crow, Yukon Territory, however, had an average TL of 36.6 mm. In addition, a single male collected as a prepupa from Kneehills Creek near Acme, Alberta is 39 mm long. This suggests a sampling bias, although there was no significant difference, possibly because the eastern sample contained more males (male specimens are commonly slightly larger than females).

Another taxon, *D. dauricus*, which is more common in Alberta, was investigated more intensively for average specimen size with respect to method of capture. The results are presented in Table 1. Similar trends were found in most species for which I have sufficient numbers of bottle-trapped specimens.

Adults of larger species of dytiscids are very quick and agile swimmers and are more difficult to collect with a dip net whereas smaller species are more commonly and easily collected with this method. For instance, at George Lake near Busby, Alberta, hours of dip net collecting yields only a few specimens of *Dytiscus* but hundreds of specimens of smaller species, whereas bottle traps have yielded in excess of 80 specimens of *Dytiscus* per trapping period (Aiken and Roughley 1985). This same phenomenon could be true for specimens of a single species of *Dytiscus* - i.e., smaller specimens have a greater chance of being caught by dip netting. Differences in TL for adult *Dytiscus* noted above are probably correlated with the method of capture.

Because of this sampling bias, I have excluded body measurements of population samples of species of *Dytiscus* from the descriptions of the species.

Table 1. Comparison of total length, greatest width, and ratio of total length - greatest width (TL/GW) of bottle trapped specimens of *Dytiscus dauricus* Gebler (Coleoptera: Dytiscidae) from George Lake, Alberta, and values reported by Larson (1975:403) for specimens captured by unspecified methods. Values are mean  $\pm$  standard deviation, with ranges in parentheses. Sample size is 28 for both samples. Lengths in mm.

Collecting method	Total Length	Greatest Width	TL/GW
Bottle trap	34.3 $\pm$ 0.8 (33.2-36.2)	18.2 $\pm$ 0.5 (17.5-19.1)	1.91 $\pm$ 0.04 (1.8801-1.98)
Various methods (Larson, 1975:403)	32.9 $\pm$ 1.3 (30.0-35.0)	16.5 $\pm$ 0.7 (15.5-18.5)	1.93 $\pm$ 0.04 (1.86-2.03)
Probability of a larger value for <i>t</i> -statistic	$p < 0.005$	$p < 0.005$	0.05-0.10

I present only the extremes of measurements of TL, GW and TL/GW for each taxon, and only as an indication of size range (Table 2). These measurements are based on specimens examined.

*Taxonomic Procedure.*— Physically large museum specimens do not travel well by mail, and cause problems if large numbers of them are assembled in one institution by borrowing— the normal practice by taxonomists. Instead of borrowing, I identified and obtained data from most specimens within the museums possessing them. Therefore, I had to learn the characteristics and limits of species before leaving for museum travel by intensive study of representatives of each species and reference to important faunistic treatments such as Larson (1975) for Nearctic species, and F. Balfour-Browne (1950), Zaitsev (1953) and Schaefflein (1971) for Palearctic taxa. In addition, other publications of more restricted scope were used to allow interpolation of other taxa treated in these references.

A problem with such on-site study is that assignment of specimens to a particular name is done comparatively quickly, with little opportunity for re-examination. Therefore, there is a pronounced possibility of misdetermination of specimens. To reduce such errors, specimens difficult to identify were borrowed from museums and studied in a manner similar to that described by Erwin (1970:9-10) and Whitehead (1972:140-141).

*Descriptive Format.*— The treatment of each taxon begins with reference to the original description of each valid name or synonym of that taxon. This is followed by information about type locality and information about label data from, and repository of, type material, if known. Most species of *Dytiscus* have a long taxonomic history. Instead of citing all references, the above information is followed by reference to Zimmermann's (1920) thorough catalogue, which provides reference to most, if not all, pre-1920 literature of importance. Any citations of a name after 1920 follow the Zimmermann

reference in chronological order, but citations of other catalogue or faunal lists are omitted.

For the valid name of each taxon, I have provided an explanation of the meaning of the name. If further explanation is needed for the status or location of type specimens, this follows the etymological section. A diagnostic combination provides a list of characteristics useful for identification of adult specimens.

Descriptions of species are provided by reference to Table 3. A tabular method of description is of great value because of reduced length and increased ease of comparison. Construction of this table follows the general format presented by Erwin (1982) except that the characters are arranged in phylogenetic sequence - *i.e.*, the first character state of each character discussed is plesiotypic while the second is apotypic. For explanation of the rationale of character state assignment see characters used in phylogenetic analysis. The description also contains reference to figures of structural features provided for each taxon.

Treatment of variation in structural features is confined to taxonomically important characters, regional differences in number of females with grooved elytra, and geographically related trends of other features. In the section on natural history, I provide information about the habitat or habitats of occurrence and some life history features for adults of *Dytiscus*. These sections are generally more extensive for Nearctic species for which I have field and laboratory observations. For most Palearctic species, I present little information; in general, information about these species is discussed in the papers which were used to compile the distribution ranges (see below) or in various papers in Korschelt (1923, 1924), Balduf (1935), Blunck (1913-1924) or Wesenberg-Lund (1912, 1943) and is not summarized here.

Distribution is shown on maps (see Distribution Maps section below for explanation of procedures used to make up the maps) and this information is generalized into a description of the range. A section entitled chorological relationships provides information about geographic co-occurrence with other species of the genus.

Many Nearctic species of *Dytiscus* have their closest relatives in the Palearctic region, while other species of either realm are members of a small clade restricted to that realm. The relative phylogenetic position of each taxon is presented in a discussion of phylogenetic relationships. A total of the number of specimens examined as well as the number of each sex is the final entry of each species treatment.

*Illustrations other than distribution maps.*— Line drawings were made with the aid of a camera lucida mounted on a Leitz stereoscopic microscope. Illustrations of median lobes of males of various taxa of *Dytiscus* were made by mounting these structures on stubs, onto which was placed two-sided tape, coating with gold and photographing with the aid of a scanning electron microscope, Cambridge Stereoscan 5150. Subsequently median lobes were removed from the stubs and placed back on the genitalia card of the specimen from which they originated.

*Distribution maps: mapping of specimen localities.*— Standard techniques were used for mapping specimen localities and consisted of finding a locality, usually in an atlas (but see below), and placing a symbol on the approximate locality on an outline map and within the region indicated (e.g. province, state, départemente, kraj, *etc.*). Within the Nearctic region, this process was straightforward and did not present many problems. All Nearctic locality records

are based on specimens seen during this study or by Larson (1975). All Nearctic locality records and all Palearctic records for which specimens were examined are indicated by filled symbols (e.g. •).

Because of logistic problems explained elsewhere, I have accepted some published records that I could not verify for some Palearctic species of *Dytiscus*, because it was determined that the historical assignment of most Palearctic taxa was in agreement with, or could be assigned to, my concepts of these taxa. Also, examination of collections within selected European museums convinced me that the degree of accuracy of assignment of most Palearctic taxa was quite high. Principally because of consistency, literature records were accepted as useful and accurate additions to knowledge of distribution of these taxa. I believe that amount of error introduced is insignificant compared to amount of information that would be lost by exclusion of literature records. Literature records for localities are also indicated by filled symbols (e.g. •).

For the most part, published records for political areas in which a specific locality is not mentioned were ignored. An exception to this is locality information for the USSR from which I saw very few specimens. In this instance, published records for political areas were accepted and are represented by open symbols which are placed over the former capital city of that political area. Most of these records were obtained from Jakobson (1905) and represent political divisions which no longer exist or are presently known by different names.

*Interpretation of presumptive locality names.*— Within the Palearctic region, assignment of locality names to particular places is more difficult and complicated than for the Nearctic region. This is because of my lack of familiarity with Palearctic localities, lack of a country or regional name on many Palearctic specimens, differences in language and transliteration, as well as problems associated with interpretation of enigmatic or cryptic label data. Procedures used when confronted with these problems include the following. 1, Inference based on the collector (I have assumed that most collectors have collected within the vicinity of their geographic home or homeland). 2, Commonly used historical interpretations of locality names were generally accepted (e.g. "Königsberg" interpreted as "Kaliningrad, Russian S.F.S.R."). 3, When a name refers to both a region and a populated place (e.g. Astrachan is both the name of a city and an oblast in Russian S.F.S.R., U.S.S.R.) I have used consistently the place name for purposes of mapping. 4, Transliteration is a particular problem with certain locality names (e.g., the Siberian city, Čita, is rendered 'Tschita' in German, 'Chita' in English, etc.). In this revision, I have followed the practice of recent international atlases, and used the official transliteration schemes adopted by the country in which localities are presently located (thus 'Čita', rather than 'Chita'; 'Astrachan' instead of 'Astrakhan'). 5, Maximum concordance among all label data is important. For example, a label in Cyrillic script was transliterated as "Jakovskoje, Spas. u., Ussuri kr." and this was interpreted as "Jakovskoje, near Spassk Dal'niy in the former Ussuri Kraj of Russian S.F.S.R., U.S.S.R." even though modern atlases list many places with the name Jakovskoje, but none in the Ussuri region. Similarly, date of collection of specimens was used as an aid in choice of locality names. The presumptive locality must have been known by that name during a time span that includes the date of collection. For instance, the specimen referred to above was collected in 1926 and the Ussuri Kraj existed as an official entity only from 1926 until 1938 (Seltzer 1962). 6, Concordance of presumptive locality with known

range of a species was used in examples where a choice among probable localities was necessary. If presented with a choice of presumptive localities, some of which were outside, and only one of which was inside the known range of a species, then the latter was accepted as correct. The known range was decided on the basis of other, unambiguous locality information. 7. When the above methods failed, an appeal was made to colleagues or other workers who have specialized knowledge of various geographic areas. Finally, if all or some of these procedures were insufficient to determine where a presumptive locality might be, then the locality name is listed under the heading "Locality not determined". In the list of specimens examined (deposited in JBWM), my interpretation of problematic localities is given, for any locality "A", as "A [=A']" for locality interpretations which I think are probably correct, and as "A [?=A']" for less certain interpretations.

*Sources of information about geographical localities.*— Many sources were used for tracing locality names. Most extensively used sources for place names were Bartholomew (1955, 1956, 1957, 1958, and 1959) and Seltzer (1962). The latter was particularly useful because of the historical treatment given various place or regional names. Most Nearctic localities were found by means of state and provincial maps. Many Canadian localities were found in Energy, Mines and Resources Canada (1980) atlas. Modern German and French language world atlases were essential. Other sources, used mainly for older names in the Palearctic region were Chisholm (1899) and Blackie (1887) which were especially useful for many 19th Century place names. Room (1979) was an invaluable source for following the changes of many place names from 1900 to 1978. Many European cities have been known by Latin names, and for interpretation of these, the work of Deschamps (1870) served admirably.

*An appeal for more complete labelling of specimens.*— Many specimens from European as well as North American collections do not include country names on the labels. Thus, an inordinate amount of time and effort is required to compile correct locality information. Two examples demonstrate the amount of time and effort wasted by taxonomists because of this oversight of collectors (previously including me).

In the course of this study, a specimen received was labelled "S. Georgia" with no further information supplied (*i.e.*, collector, date, or country). This locality information could be variously interpreted as: 1) southern Georgia, U.S.S.R., 2) southern Georgia, U.S.A., 3) south of Georgia, Vermont, U.S.A., 4) Strait of Georgia, British Columbia, Canada, or 5) South Georgia, an island in the South Atlantic Ocean. Application of procedure 6 noted above meant that the U.S.S.R. locality was most likely the correct one.

The second example concerns various abbreviations used for States and Provinces. For instance, the current abbreviation used by the U.S. Post Office for the Province of Alberta is "AB" while the abbreviation most commonly used by Canadians is "Alta". Both of these abbreviations have been and are being used by collectors without any indication of country of origin.

During a recent trip to Europe, a colleague talked to a European lepidopterist who had traded specimens with workers in Alberta. This colleague was asked about the incredible diversity of butterflies occurring at "Alta, Colorado". Not realizing that "Alta" was an abbreviation for the name of a province in Canada, the collector had made a choice among the four "Alta" localities which he could find in his sources of information about North American geography: Alta, Colorado; Alta, California; Alta, Iowa; and Alta, Utah, all of which are in the wrong country.

Problems associated with interpretation of label data and locality information probably account for a good deal of reluctance of some entomologists to study the fauna of other regions. This situation runs counter to the developing trend in insect systematics to consider the total fauna of groups so that more information is available for phylogenetic and zoogeographic analysis. Much is lost and confusion and conflicts occur when a common fauna (in this example, Holarctic) is studied by vicariant systematists working in isolation from one another. Part of the problem can be solved so easily by proper labelling of specimens.

*Ranking: subgenera.*— Subgenera are taxonomically useful and provide the basis for organization of species within large, divergent genera or within smaller genera which encompass a large amount of divergence (Ball and Roughley 1982). This utility is enhanced if different subgenera occupy different adaptive zones. Each subgenus however, must represent a natural evolutionary unit, *i.e.*, it must be monophyletic.

I have recognized no subgenera within *Dytiscus*. Subgenera recognized previously are nomenclaturally invalid and/or do not represent phylogenetically distinct clades. As well, I can discern no new adaptive zones of member taxa, nor does any group of species diverge sufficiently from the basic structural pattern enough to warrant subgeneric assignment.

*Ranking: species groups.*— Use of species-groups provides increased information and convenience without the demands and increased complexity of formal nomenclature. They represent an abbreviated notation for a group of species which are defined in a more complex manner. For instance, the group of species of *Dytiscus* which possess acuminate metacoxal processes are referred to herein as the *D. dauricus*-group. See Lindroth (1969:xxiii-xxiv) for further discussion of use of species-groups.

I have used species-groups for small monophyletic clades because of communicative value and ease with which these smaller groups are discussed in treatments of classification; however, these species-groups are not characterized formally. I have not used any uniform manner in selecting the nominate taxon of species-groups. Instead, I have used the name of that taxon which represents a mental image of the species-group to me (Fig. 52).

*Ranking: species.*— Most animal taxonomists subscribe, at least nominally, to some form of Mayr's (1942) "biological" species definition. This, however, represents a theoretical ideal of how animals should behave, and is most difficult to test or even infer consistently or uniformly from the patchy samples characteristic of most analyses of taxa. After comparing and contrasting various species concepts used by botanists and zoologists and their uses and values in practice, Cronquist (1978:3) suggested that: "Species are the smallest groups that are consistently and persistently distinct, and distinguishable by ordinary means." Cronquist further details problems with strict use of a narrow or even a single species definition. Similarly, Hammond (1981a and b) has suggested that concepts of species and speciation built from experience with large, mobile vertebrates with low reproductive rates do not apply well to many insect groups.

The more important goals of the brief discussion above are to point out the need for a re-evaluation of species concepts by practicing animal taxonomists. Of paramount importance is the need for every taxonomist to state clearly the criteria for species recognition which they have used.

My study of taxonomic status of population samples of species of *Dytiscus* was hampered by low numbers of most samples, and samples from widely

separated areas. Such disparate samples probably come about because of lack of collecting attempts in certain areas, shortage of museum storage space, difficulty of collecting large fast-swimming beetles, seasonal occurrence of adults, relatively low levels of abundance, and bias of certain collecting techniques (see Measurements). While it is true that most species of *Dytiscus* so far encountered in the field are common to very abundant in the correct habitat at the correct time of year, it is also true that they are always at a relatively low density [e.g. see James (1970) for *D. fasciventris* and discussion of natural history in my treatment of *D. cordieri*]. Low density is almost certainly a result of the status of these beetles as major predators within most pond ecosystems.

I required a practical and useful means of delimiting species which could circumvent such problems. The most useful criteria I have found for delimitation of species of *Dytiscus* is form of apex of median lobe and sympatry. Characteristics of the median lobe are distinctive, so that even closely related species are differentiated consistently, and median lobes of male specimens of the same species from widely separated parts of the species range are similar. For instance, the median lobes illustrated in Figs. 18D and 19A are close to the extremes of variation found within a single putative species (in this example *D. circumcinctus*), yet the respective specimens are from Edmonton, Alberta, Canada and Berlin, Germany. Females were associated on the basis of co-occurrence with males and by general similarity in body shape and colour pattern. Although not used in my study, Régil and Salgado (1984) have shown useful taxonomic characters in the form of the female genitalia. Sympatry of divergent forms was used as a corroborative test of species status. However, in examples for which no sympatry is known (e.g. *D. habilis* - *D. marginicollis*; *D. semisulcatus* - *D. sharpi*) difference in form of median lobe is considered sufficient for assignment to species status.

*Ranking: subspecies.*— Mayr (1963, 1969) and Simpson (1961) provide thorough analyses of theoretical and genetic aspects of subspecies and subspeciation. Kavanaugh (1979:92-94) and Lafontaine (1982:9-10) presented balanced and valuable discussions of use of subspecific rank, and more importantly have expressed their practical criteria for recognition of subspecific status. I have accepted, amalgamated, and used the criteria of the latter two authors. Subspecific names are used for sets of population samples which are: 1, independent or isolated evolutionary units; 2, presently differentiated from other conspecific units but excluding differences thought to be ecophenotypic; 3, sufficiently phenotypically distinct that, except for similarity of aedeagus of male specimens, they approach the amount of phenotypic divergence found among any two closely related species; and 4, of significance in analysis of historical zoogeography. Such populations are inferred to be isolated at present only by geographical gaps in range. If this barrier to gene flow is maintained for a sufficient period of time, then it is predicted that these populations will diverge sufficiently to preclude future mixing of genetic information. In short, subspecies status is used for inferred incipient species status.

The amount of meristic variation observed in most species of *Dytiscus* is quite low. I believe this is due in large part to various aspects of life history of these species, such as dispersal, which lead to panmixis. Because of the normally uniform nature of most species, phenotypically distinct populations are quite apparent, i.e., they stand out. Therefore, my procedure for assignment of rank is recognition of subspecific allopatric populations of consistently distinct phenotype, but of which male specimens have sufficiently similar forms

of the apex of the median lobe of the aedoeagus to be included in the same species.

*Intraspecific categories other than subspecies.*— Literature concerned with taxonomy of European species of *Dytiscus* is replete with names for such infraspecific categories as variety, form and aberration. As such, and provided that they are truly intended as something other than subspecific levels, they are outside the jurisdiction of the *International Code of Zoological Nomenclature* and each taxonomist is free to deal with them as seems appropriate. Within species of *Dytiscus* these names are used predominantly to express differences in sulcation of the elytra of female specimens. For instance, female specimens of *D. marginalis marginalis* vary in degree of elytral sulcation, from those with distinct elytral sulci to those with no trace of sulci, with every conceivable intermediate. However, the latter category is decidedly less numerically common in collections. These respective forms are generally named *forma typica*, var. *conformis* Kunze (even though Kunze described *conformis* as a distinct species), and var. *semicostatus* Reineck.

I believe that use of such names, some of which have no obvious descriptive value, to be retrogressive and needless. If Nearctic and other Palearctic species were all treated in a similar manner, then proliferation of names would be extensive, but our understanding of this intriguing phenomenon would, I think, be diminished and obscured. In an attempt to increase the descriptive and therefore communicative value of variation in degree of elytral sulcation I have not recognized any names below the rank of subspecies and instead I have discussed it as occurring in two states: sulcate and non-sulcate. The former state includes all specimens with any trace of sulcation visible on an elytron. Use of these two states allows clear and unambiguous expression of any geographical pattern in elytral sulcation without detailed knowledge of the taxonomic history of a species.

## STRUCTURAL FEATURES

### Sexual dimorphism

Adults of *Dytiscus* exhibit a number of characters which are sexually dimorphic. Excluding male and female genitalia, the most obvious of these are the following: 1, male specimens are broader and longer on average; 2, pronota of male specimens are wider at the base and less narrowed anteriorly; 3, profemora of males are bowed along their length and are more robust and more deeply emarginate ventrally; 4, male specimens have two tufts of long setae at the base of each profemur compared to one tuft on female specimens; 5, male protibiae are more robust and widened basally; 6, three basal protarsomeres of male specimens are laterally expanded and form a large subcircular acetabulum, with tarsomere I bearing two very large and numerous small suckers and tarsomeres II and III each with only numerous smaller suckers; 7, male mesotibiae are slightly longer and very slightly more robust; 8, male specimens with three basal mesotarsomeres elongated and widened to form an acetabulum, these tarsomeres bearing numerous small suckers; 9, some adult females of some species have 10 longitudinal narrow grooves or sulci on each elytron; and 10, male specimens possess natatory setae on both the anterior and posterior faces of both the metatibiae and basal metatarsomeres, while female specimens bear natatory setae on the anterior faces of the metatibiae and on the posterior faces of basal metatarsomeres, only.

*Body size and shape.*— Despite the limitations of measurements of body length (see Measurements), I have made limited use of total length (TL) in

distinguishing among members of certain pairs of species, especially where there is no overlap among the adults in size. However, TL is used also in examples where the majority of specimens of a species tend to be larger or smaller than the majority of specimens of another species treated in the other rubric of a couplet in the key. Ranges of lengths of specimens examined are shown in Table 2 for each species of *Dytiscus*. In general, the most common length of specimens is toward the upper end of the range, but there are exceptions (e.g. compare information in Tables 1 and 2 for Nearctic specimens of *D. dauricus*). Body shape (TL/GW) is relatively uniform among species of *Dytiscus* (Table 2, except *D. latissimus*). Differences in body shape are used in certain species pairs where there is no overlap of range in this ratio.

*Head.*— Five taxonomic characters of the head are used. The anterior margin of the clypeus of specimens of most species is linearly transverse or slightly concave, whereas in specimens of *D. harrisii* and *D. latissimus* it is distinctly bisinuate. The posterior margin of the clypeus is normally on the same plane as the frons. In female specimens of *D. dauricus*, however, it is distinctly and abruptly raised above the level of the anterior margin of the frons, and is quite useful for recognizing female specimens of this species.

All members of *Dytiscus* have a more or less distinct chevron-shaped pale mark on the frons between the eyes. Typically the lateral arms of the chevron are not extended antero-laterally to the antennal bases, but in some species where this occurs in most specimens, this character state is taxonomically useful. In some specimens, yellow coloration associated with increased chevron size extends posteriorly from the antennal bases along the inner margins of the eyes and thus forms an inverted M-like mark on the frons. However, members of only one species, *D. circumcinctus*, were observed to have the entire eye ringed with yellow on the dorsal surface.

Members of all species of *Dytiscus* have lateral yellow bands on the pronotum. Anterior and posterior bands are or are not present. Specimens of any given species vary in colour and, generally, lighter specimens of a taxon which would normally show no trace of, for instance, an anterior pronotal band, have a very narrow yellowish or reddish band. Characterization of relative width of anterior or posterior bands is quite important. For instance, in couplet 3 of the key to Nearctic species, the alternatives are anterior band less than 0.4 versus more than 0.5 width of lateral band. I have not recorded a specimen of either category which is very close to these measurements. For instance, most specimens following the first alternative are in the range of 0.3 or less and those following the second alternative are in the range of 0.6 or more. Therefore, the values used in the key were chosen to allow for more variation than recorded and to avoid a strictly comparative character such as anterior pronotal band wider versus narrower. Even if exceptional specimens are encountered, subsequent comparison to the diagnostic combination of each species should allow discovery of misidentification.

The pronotum of most specimens of *Dytiscus* has a longitudinal, shallow channel near the lateral margin. When this character state is present the pronotum is described as explanate. Reduction or lack of an explanate pronotum is characteristic of the members of the *D. hybridus*-group and of male (but not female) specimens of *D. cordieri*.

*Legs.*— Length of the apical pro- or mesotarsal segment is used commonly in the keys as an aid for determination, but in the form of a comparative rather than as an absolute numerical value. Pro- and/or mesotarsal claws are longer or shorter than pro- or mesotarsomere V, or the values are converted to a

proportional value. Proportional length of protarsomere V to width of protibia, measured at the widest point, allows establishment of two species-specific categories for males of some species. Relative number of punctures on the anterior surface of protarsomere V is also used.

Male specimens of *D. hybridus* and *D. marginicollis* are distinctive in that mesotarsomeres II and III lack suckers from a small longitudinal area. Male specimens of all other species of *Dytiscus* have suckers evenly distributed over mesotarsal acetabula.

Coloration of metacoxal plates follows that of pterothoracic sterna discussed below.

Form of the metacoxal process varies considerably among sets of species but relatively little within species and therefore is of great taxonomic value for establishing major sections in the key. The inner margin of a metacoxal process is convex (e.g. Fig. 21A), or concave (e.g. Fig. 22K). Apically the metacoxal process is more or less rounded (e.g. Fig. 21A), or the lateral margins form an acute angle (e.g. Fig. 22A), or the apex is drawn out into an elongate acuminate process of varied length (e.g. Fig. 22K).

Shape of the apex of the metatrochanter varies extensively within some taxa, is sexually dimorphic in some, and is characteristic in still others. When used as a taxonomic character, it occurs in two states: apex broadly rounded, or drawn out into a fine point apically (acuminate).

*Elytra*.— Colour of elytra of most specimens is piceous to black with lateral yellow stripes. Many specimens have the lateral stripe abruptly curved inward pre-apically to form a more or less obscure subapical fascia, but in specimens of *D. verticalis* this fascia is quite distinctive because it is uninterrupted, broad, and highly contrasted with elytral ground colour. Elytra of some specimens of *D. lapponicus* have a yellow ground colour with infuscation reduced to linear rows of small dots.

The elytral epipleuron is exceptionally expanded laterally in specimens of *D. latissimus* and accounts for much of the unique width and body shape characteristic of this species (Table 2). Specimens of *D. harrisii* have the epipleuron slightly widened but not nearly as greatly as in the former species. No other species shows expansion of the elytral epipleuron.

Elytra of some female specimens are sulcate. Sulci are narrow longitudinal depressions of the surface cuticle and each sulcus is separated from its neighbour by an inter-sulcal ridge. No female specimens of the Nearctic *D. verticalis*- or *D. hybridus*-groups that I have seen were sulcate. Among other species groups the proportion of sulcate and non-sulcate females varies greatly. Only in *D. carolinus* and *D. latissimus* were all female specimens observed sulcate. No sulcate females were seen of some Palearctic species (e.g. *D. delictus*), but this is probably because of the low numbers of specimens available for study. Relative length of elytral sulci is not used as a taxonomic character, but there is a phylogenetic trend toward increasing sulcal length. Members of certain taxa with very long sulci have distinctive patterns. For instance, sulcate female specimens of *D. dauricus* have inter-sulcal ridges VII and IX (numbered from suture) curved toward each other and in contact, thus V-shaped, apically. The shorter intermediate ridges VIII and IX do not meet apically. Sulcate females of *D. alaskanus* have the respective members of each pair of ridges curved toward and apically in contact such that each pair forms its own exaggerated V-shape.

*Pterothoracic and abdominal sterna*.— Colour pattern of abdominal and pterothoracic sterna is diagnostic given an understanding of infraspecific variation, which is relatively low among species of *Dytiscus*. Extremes in

pattern are shown in Figs. 7 to 13. The median lobe of male specimens at the end points of colour variation were examined carefully to determine that they did indeed belong to a given taxon. In these figures, infuscation is shown as black, yellow as white, and red as various densities of stippling. The darker the red coloration, the more dense the stippling. These figures are mostly composite, *i.e.*, they represent the lightest or darkest sterna respectively of series of species studied intensively. As such they should represent close to the extremes of specimens which will be encountered. This is somewhat dependent on the total number of specimens that I have examined. For instance, I have greater confidence that the limits of variation are approached in the representation of *D. marginicollis* (972 specimens examined), than in that of *D. persicus* (16 specimens examined). Important character states are presence or absence of red coloration, whether or not the abdominal and pterothoracic sterna are unicolorous piceous or black or yellow versus yellow with infuscated areas and, if the latter, then the relative amounts and positions of the infuscations.

*Median lobe of aedoeagus.*— Exceptionally diagnostic and uniform characteristics are in shape of the apex of the male median lobe (Figs. 14-20). Of specimens examined, variation within species is insignificant. I have not used length of the median lobe as a taxonomic character because this is probably correlated with variation in total body length of specimens (see Measurements). Important character states of median lobe shape are: 1, comparative deflection of apex from line formed by basal portion of median lobe; 2, rounded versus irregular apex; 3, presence or absence of apical knob; 4, presence or absence of subapical, lateral notches; 5, width of apical knob relative to preapical width of shaft; 6, relative position (dorsal/ventral) position of lateral bead or ridge; and 7, overall similarity to that shown in the scanning electron micrographs.

*Distribution.*— Perhaps the most desirable and easiest couplets to use are those which separate eastern and western species (*e.g.* *D. sharpi* and *D. semisulcatus*). The degree of confidence in the use of such couplets is related to amount of gap between ranges and degree to which the range of a species is known or at least the degree to which it can be predicted. When this confidence is fairly high, I have not hesitated to use range as a character of equal value to structural features. In the keys the geographic range of a species or subspecies is not used as the only character state because of numerous specimens with no or only cryptic label information.

## CLASSIFICATION

### Genus *Dytiscus* Linnaeus

*Dytiscus* Linnaeus 1758:411. Type species - *Dytiscus marginalis* Linnaeus 1758:411, designated by Latreille 1810:426, attributing the species to Fabricius 1775:230. Curtis (1826:99), Westwood (1838:9), Crotch (1873:406), Guignot (1946:118), Leech (1948:413), J. Balfour-Browne (1960:252), Guignot (1961:856) and Nilsson *et al.* (1989:294) cite *D. marginalis* as type species. Hope (1839:131, 137), Duponchel (1845:154), Jacquelin du Val and Migneaux (1857:77), and Thomson (1859:12) all have designated independently *Dytiscus latissimus* Linnaeus 1758:411 as type species.

*Dytiscus* Müller 1776:69. Incorrect emendation; rejected and invalid generic name (Opinion 619, 1961).

*Macrodytes* Thomson 1859:12, 1860:41. Type species - *Dytiscus marginalis* Linnaeus 1758:411, by original designation. Therefore *Macrodytes* Thomson is a junior, objective synonym of *Dytiscus* L. Guignot (1961:857, "...désigné ici.") subsequently and therefore invalidly designated *D. marginalis* L. as type species of subgenus *Macrodytes*.

*Leionotus* Kirby 1837:76. Type species - *Dytiscus conformis* Kunze 1818:58 (junior synonym of *D. marginalis* L.), designated by Hope (1839:131), who attributed the species name to Stephens (1828:87). Therefore *Leionotus* Kirby is a junior, subjective synonym of *Dytiscus* L.

*Dyticopsis* Houlbert 1934:134. Type species -not designated. This name is not available because the original description was not accompanied by type fixation (ICZN 1985, Art. 13b).

## Description (Adults)

Size large, TL 22.0 to 44.0 mm, body form ovate (TL/GW 1.76 to 2.10 except *D. latissimus* 1.55 to 1.62), outline continuous, widest just behind middle. Colour dark brown to piceous, many specimens with greenish cast, with yellow or reddish markings.

Surfaces shining, with singular isodiametric sculpture, microlines very fine and difficult to see except at very high magnifications; surface of some specimens dulled by dense accumulation of coarse pores at apex and/or base of elytra, laterally on pronotum, or on sulci of sulcate females. (Detailed studies of adult structure of *D. marginalis* are provided by Buhlmann [1923:16-79] and F. Balfour-Browne [1932:29-51]).

**Head.**— Large, prognathous, inserted firmly into thorax, without raised carinae. Labrum excised on anterior margin (except nearly truncate in *D. latissimus*), yellow to red, with brush of fine short hairs in emargination. Labro-clypeal suture distinct, evenly curved (except bisinuate in *D. harrisii*). Clypeus distinct, yellow to red, clypeo-frontal suture present. Frons of most specimens dark brown to piceous or black, most specimens with yellow to red chevron and yellow to red markings over antennal bases and, on many specimens, on inner margins of eyes. Chevron of few specimens extended to antennal bases. Vertex short, dark brown to piceous or black. Occiput normally inserted into thorax. Eyes large, anterior margin not emarginate. Palpi and antennae yellowish to reddish-brown, articles of many specimens infuscated apically. Antennomeres elongate, glabrous, otherwise unmodified. Mandible with retinacular and two terebral teeth, and with row of stiff, short setae ventrally. Maxilla with palpomeres elongate, glabrous, otherwise unmodified. Lacinia with apex acute and abruptly bent, setose on inner margin only. Galea with apex bluntly pointed and abruptly bent. Labium with palpomeres elongate, glabrous, otherwise unmodified. Mentum distinct, deeply emarginate at middle, with two low lobes in emargination, without setae. Submentum slightly wider than mentum, without setae. Gula narrowest just posterior to contact with submentum, wider apically, at narrowest 0.25 to 0.33 width of prementum, without setae. (Further structural information about head in Sharp [1882:203-215], Buhlmann [1923:17-33], F. Balfour-Browne [1932:29-30], and Guignot [1931b:13-19]).

**Thorax.**— **Pronotum** transverse, without carinae, with lateral margins acute but not margined, wider at base than at head, with lateral outline rounded, antero-lateral margins produced anteriorly as rounded lobes on either side of head. Dorsally glabrous, with base continuous with and overlapping bases of elytra, posterior margin more or less bisinuate on each side, majority of specimens explanate with linear depression laterally extended from anterior lobes to base, disc dark brown to black with lateral yellowish bands, some specimens with anterior and/or posterior yellowish to reddish bands. Ventrally with prosternum markedly compressed by enlarged procoxae, procoxae confluent, open-bridged (Bell 1967, Evans 1977, Baehr 1979). Prosternal process with ventral surface convex basally to flat apically, apex broadly rounded, marginal bead complete except apically. (Further details of prothoracic structure in Sharp [1882:215-222], Evans [1977, 1985] and Baehr [1979]). **Mesosternum** with mesocoxa of complex-type of Bell (1967), metepisternum in contact with mesocoxal cavity (Dytisci complicati of Sharp 1882:964). (Further details of structure of mesosternum in Sharp [1882:222-228] and Evans [1977]. **Metasternum** with short broad notch for reception of prosternal process, metasternal wing with antero-lateral margin not straight, metasternum wide, most specimens with shortest distance from mesocoxa to metasternum greater than width of metacoxa measured along same line; metasternal wing not extended to epipleuron. Metacoxae of incomplete-type of Bell (1965), metacoxal plates transverse, length approximately 0.5 width. Metafurca (metendosternite) with space between anterior rami narrow and short, base wide and transverse, with arm at each end (Crowson 1938, 1944, F. Balfour-Browne 1944, 1961, 1967, Riha 1955:391-393). (Further details on thoracic structure in F. Balfour-Browne [1932:30-36, 1965, 1967]).

*Proventriculus*.— Bowl- or calyx-shaped, outer (main) lobes triangular, ciliate, and without teeth, inner (intermediate) lobes triangular (F. Balfour-Browne 1934, 1944).

*Legs*.— Short, broad, sexually dimorphic in setation. Anterior and middle legs quite short, with marked sexual dimorphism of form, in repose retracted into prosternal-mesosternal cavity. Relative length (longest to shortest): femur, tarsi, tibia. Hind legs longer, without sexual dimorphism of form, strikingly modified for aquatic life. Relative length: tarsi, femur, tibia. (Further details of structure of legs in Sharp [1882:234-239, 146-257], Buhlmann [1923:48-64], Guignot [1931b:34-44], and F. Balfour-Browne [1950:259-263]).

*Elytra*.— Continuous with outer margin of pronotum at base, widest just behind middle, apices rounded. Dorsal surface shining or dulled by dense, coarse punctation basally, apically and/or laterally, long fine setae on postero-lateral margin. Dark brown to black, many specimens with greenish cast, with lateral yellow margins, some specimens with sublateral transverse fascia. Lower surface without sublateral carina and ligula; subapical binding-patch of modified setae present (Hammond 1979).

Males with upper surface without sulci, female with or without sulci. Sulci sub-basal, in form of narrow shallow longitudinal trenches, ending from 0.5 to about 0.85 of elytral length. (Further details of structure of elytron in Sharp [1882:241-243], Buhlman [1923:68-70], Guignot [1931b:28-31] and Hammond [1979]).

*Metathoracic wings*.— Normally developed, no specimens observed to be brachypterous. Wedge cell normally developed. Oblongum cell in shape of parallelogram, with M-vein attached anterior to middle. Distinct area of modified dense setae along posterior margin of cubitus vein near wing margin. (Further details of structure of flight wing in Sharp [1882:243-246], Forbes [1922, 1926], Buhlman [1923:64-67], Guignot [1931b:32-33], Goodliffe [1939], F. Balfour-Browne [1944], Hammond [1979] and Ward [1979]).

*Abdomen*.— Dorsally with basal pleuron transversely grooved. Apical two pleura with stigmata markedly enlarged and transversely elliptical, these pleura densely covered with long setae. Sterna glabrous except some specimens with long fine scattered setae on last visible sternum. Various in colour, unicolorous black or yellow or marked with black, yellow, or red. Proportional length of visible sterna (longer to shorter): last, second, third, fourth, fifth and first subequal at epipleuron. (Further details of structure of abdomen in Sharp [1882:239-241], Buhlmann [1923:72-77], F. Balfour-Browne [1932:50-51] and Guignot [1931b:44-49]).

*Aedoeagus*.— Similar to that of *Hydaticus* (Roughley and Pengelly 1982:256-257, 295, Figs. 4 and 5), except as follows: 8th sternum with deep narrow emargination, 9th pleuron with small longitudinal sclerite on membrane, median lobe without lateral flanges, paramere without flame and with setae on antero-dorsal margin, preputial covering not complete to apex, incised, and epipenite absent. (Further details of structure of aedoeagus are in Demandt [1924:209-275], Guignot [1931b:49-58] and F. Balfour-Browne [1932:40-45; 1950:255-256]).

*Ovipositor*.— Apical sternum with deep narrow emargination extended to base, central portions membranous. Paraproct triangular with posterior margin membranous centrally. Valvifer articulated with stylomere I apically, of two lateral elongate struts joined by membrane. Vulval sclerite lamellate, without setae, inserted into stylomere I ventrally. Stylomere I elongate, sclerotized, acute apically, without setae and cultriform in shape. (Further details of structure of ovipositor in Demandt [1924:151-209], F. Balfour-Browne [1932:46-50], Guignot [1931b: 58-67] Burmeister [1976, 1980] and Régil and Salgado [1984]).

*Geographical distribution*.— The genus *Dytiscus* is Holarctic, ranging from Arctic habitats in the north to the northern slopes of the Himalaya and North Africa, in the Old World; and to the edge of the Tropics, in Guatemala in the New World.

*Chorological and phylogenetic relationships*.— The sister genus of *Dytiscus* is the Australian genus *Hyderodes* Hope. The two genera are thus distributed vicariously.

*Species groups*.— The 26 species of *Dytiscus* are arranged in six groups, as indicated in the following list. The species-groups which I recognize are based on the reconstructed phylogeny (Fig. 52). These are:

- |                              |                          |

### Key to Adults of Nearctic Species of *Dytiscus* Linnaeus

1	(0)	Metacoxal process with inner margin convex, apex rounded to obtusely angulate, but not acuminate (Figs. 21A-E, H-K) .....2
1'		Metacoxal process with inner margin concave, apex acutely angulate, more or less acuminate (Figs. 22F-H) .....12
2	(1)	Clypeus with anterior margin shallowly but distinctly bisinuate (Fig. 23A); pterothoracic sterna predominantly piceous to black, metacoxa and abdominal sternum I marked with yellow, sterna II to V or II to VI with reddish markings (Fig. 7B)..... ..... <i>D. harrisii</i> Kirby, p. 433
2'		Clypeus with anterior margin straight or slightly concave; ventral markings various.....3
3	(2')	Pronotum with anterior yellow band less than 0.4 width of lateral bands (Figs. 1A, D, 2C-E) .....4
3'		Pronotum with anterior yellow band of most specimens more than 0.5 width of lateral bands (Figs. 1B, C).....9
4	(3)	Pterothoracic and abdominal sterna piceous to black.....5
4'		Pterothoracic and/or abdominal sterna with yellow or reddish markings.....7
5	(4)	Pronotum with lateral margins not explanate; males with mesotarsomeres II and III with median glabrous area ventrally; females not sulcate ..... ..... <i>D. hybridus</i> Aubé, p. 434

- 5' Pronotum with lateral margins explanate; males with mesotarsomeres II and III with uniform distribution of ventral suckers; females sulcate or not .....6
- 6 (5') Size larger, TL from 29.6 to 36.0 mm; elytron of most specimens with yellow subapical transverse fascia (Fig. 1A); females not sulcate.....*D. verticalis* Say, p. 431
- 6' Size smaller, TL from 22.0 to 26.1 mm; elytron without yellow subapical transverse fascia (Fig. 2C); females sulcate .....*D. carolinus* Aubé (in part), p. 446
- 7 (4') Metepisternum, metasternal wings and metacoxae predominantly piceous to black, abdominal sterna black with reddish to piceous markings (Fig. 8D); distribution more southern, Atlantic Coast (Connecticut, south to Georgia), Gulf Coast, and northward along Mississippi River (Fig. 31) .....*D. carolinus* Aubé (in part), p. 446
- 7' Metepisternum, and metacoxae predominantly testaceous, abdominal sterna testaceous with black markings (Figs. 9A, B); distribution more northern and western .....8
- 8 (7') Males with protarsal claws of most specimens longer than protarsomere V (Fig. 23C); females with mesotarsal claw longer than mesotarsomere V (Fig. 23E); pronotum more broadly margined with yellow (Fig. 2E); distribution west of Rocky Mountains from central California to northern British Columbia (Fig. 33) .....*D. hatchi* Wallis, p. 449
- 8' Males with protarsal claws of most specimens shorter than protarsomere V (Fig. 23D); females with mesotarsal claws shorter than mesotarsomere V (Fig. 23F); pronotum more narrowly margined with yellow (Fig. 2D); transcontinental in northern North America (Fig. 32).....*D. fasciventris* Say, p. 447
- 9 (3') Pronotum distinctly explanate; protarsal claws subequal to protarsomere V; abdominal sterna yellow with basolateral infuscations (Fig. 9A, B) .....8
- 9' Pronotum not or indistinctly explanate; protarsal claws much shorter than protarsomere V; abdominal sterna predominantly yellow (Fig. 9C) or predominantly black with various coloured markings (Fig. 7D, 8A) .....10
- 10 (9') Pterothoracic and abdominal sterna testaceous to pale rufous (Fig. 9C); frons of most specimens with chevron extended to antennal bases (Fig. 23B); females with pronotum shallowly explanate, some specimens with elytron sulcate .....*D. cordieri* Aubé, p. 456
- 10' Pterothoracic and abdominal sterna with extensive infuscation (Figs. 7D, 8A); frons with chevron not extended to antennal bases (e.g. Fig. 23A); females with pronotum not explanate, elytron not sulcate .....11
- 11 (10') Pronotum with discal infuscation narrower than lateral yellow band (Fig. 1C); male with mesotarsomeres II and II with uniform distribution of suckers ventrally; distribution as in Fig. 28 .....*D. habilis* Say, p. 437

- 11' Pronotum with discal infuscation wider than lateral yellow band; male with mesotarsomeres II and III with median glabrous area ventrally; distribution as in Fig. 27 .....  
.....*D. marginicollis* LeConte, p. 435
- 12 (1') Eye enclosed dorsally by narrow yellow band, or, some specimens with band narrowly broken near inner posterior margin of eye; pterothoracic and abdominal sterna I to III very narrowly infuscate in some specimens (Fig. 11D) .....  
.....*D. circumcinctus* Ahrens, p. 477
- 12' Eye not enclosed dorsally by narrow yellow band, some specimens with inner margin margined with yellow or red; pterothoracic sterna with at least metasternum medially infuscate (Figs. 12A, B), abdominal sterna various in colour pattern.....13
- 13 (12') Male with apical portion of median lobe sinuate laterally and apical knob distinct in dorsal view (Fig. 19C); females with postero-median margin of clypeus distinctly raised above level of frons along clypeal suture; sulcate females with ridges of sulci VII and X fused apically, and those of VII and IX not fused apically; size larger, TL from 29.7 to 40.0 mm. ....  
.....*D. dauricus* Gebler, p. 483
- 13' Male with apical portion of median lobe evenly curved laterally and apical knob indistinct in dorsal view (Fig. 19B); females with postero-median margin of clypeus on same level as frons along clypeal suture; sulcate females with ridges of sulci VII and X, and of VIII and IX fused apically forming a 'V-V' pattern (Fig. 5A); size smaller, TL from 22.6 to 30.2mm.....*D. alaskanus* J. Balfour-Browne, p. 481

Key to Adults of Palearctic Species of *Dytiscus* Linnaeus

- 1 (0) Metacoxal process with inner margin convex, apex rounded to obtusely angulate, not acuminate (Figs. 21F, G, L-N).....2
- 1' Metacoxal process with inner margin convex, apex acutely angulate and more or less acuminate (Figs. 22E-N).....11
- 2 (1) Pronotum with anterior and posterior yellow bands absent, OR, less than 0.33 width of lateral band (Figs. 2A, B, 3B, C) ....3
- 2' Pronotum with anterior and posterior yellow bands present and at least 0.50 width of lateral band (Fig. 3D) .....6
- 3 (2) Pterothoracic sterna piceous to black (Figs. 8B, C); smaller specimens, 24 to 30 mm).....4
- 3' Pterothoracic sterna predominantly yellow (Figs. 9D, 10A); larger specimens, 28 to 39 mm.....5
- 4 (3) Metatrochanter with apex rounded (Fig. 21F); body narrowly oval (TL/GW 1.97 to 2.01); distributed from Europe, east to Kazakh SSR (Fig. 29), and New Zealand.....  
.....*D. semisulcatus* Müller, p. 444
- 4' Metatrochanter with apex acuminate (Fig. 21G); body broadly oval (TL/GW 1.84 to 1.94); distributed in Japan, Maritime USSR, northeastern China (Fig. 30).....  
.....*D. sharpi* Wehncke, p. 445
- 5 (3') Body oblong (TL/GW 1.98 to 2.00); male with protarsomere V about 1.3 length of longer claw (Fig. 23G), and about 30 punctures on anterior surface; smaller specimens, 28 to 35 mm; distributed in Italy, Corfu, Yugoslavia (Fig. 35) .....  
.....*D. mutinensis* Pederzani, p. 458
- 5' Body more elongate (TL/GW 1.84 to 1.95); male with protarsomere V about 1.5 length of longer claw (Fig. 23H), and about 60 punctures on anterior surface; larger specimens, 32 to 39 mm; distributed from Europe to Transcaucasia, Asia Minor and Syria (Fig. 36) .....  
.....*D. dimidiatus* Bergsträsser, p. 459
- 6 (2') Metacoxal process with apex rounded (Figs. 21N, 22D) .....7
- 6' Metacoxal process with apex acute (Figs. 22A-C) .....8
- 7 (6) Metatrochanter with apex acuminate (Fig. 21N); male with protarsomere V about 1.3 times width of protibia; male with median lobe broadly rounded at apex (Fig. 17B); female with mesotarsomere V about 2.0 times length of IV (Fig. 23I); most females with elytron sulcate; distribution circum-Mediterranean (Fig. 37).....  
.....*D. pisanus* Laporte de Castelnau, p. 461
- 7' Metatrochanter obtusely rounded or acute (males, Fig. 22D); male with protarsomere V about equal in length to width of protibia; male with median lobe notched laterally at apex (Fig. 18B); female with mesotarsomere V about 1.5 times length of IV (Fig. 23J); no sulcate females known; distributed in Maritime USSR (Fig. 40).....*D. delictus* (Zaitzev), p. 471
- 8 (6') Venter with at least abdominal sterna II, II and VI with large, transverse, baso-lateral infuscation (Fig. 10D, 11A) .....9

- 8' Venter with abdominal sterna II to V without baso-lateral infuscation, or, with only narrow baso-lateral infuscation (Fig. 10C) .....10
- 9 (8) Head with chevron extended antero-laterally to yellow spot at antennal base; distributed in Maritime USSR and Japan (Fig. 38) .....*D. marginalis czerskii* Zaitsev (in part), p. 469
- 9' Head with chevron not extended antero-laterally, not connected to yellow spot at antennal base; distributed in Caucasus Mountains, Transcaucasia and Crimean USSR, northeastern Turkey and Iran (Fig. 39).....  
.....*D. persicus* Wehncke, p. 470
- 10 (8') Head with chevron extended antero-laterally to yellow spot at antennal base; distributed in Maritime USSR and Japan (Fig. 38) .....*D. marginalis czerskii* Zaitsev (in part), p. 467
- 10' Head with chevron not extended antero-laterally, not connected to yellow spot at antennal base; distributed from Portugal and southern Spain north to Scotland and east Siberia (Fig. 38).....  
.....*D. marginalis marginalis* Linnaeus, p. 467
- 11 (1') Elytron with epipleuron greatly widened into a flange (Fig. 4B); clypeus of most specimens with anterior margin shallowly bisinuate; distributed from France through Ukrainian SSR to western Siberia (Fig. 41).....  
.....*D. latissimus* Linnaeus, p. 476
- 11' Elytron with epipleuron not widened into flange; clypeus with anterior margin evenly curved.....12
- 12 (11') Pronotum very broadly margined with yellow, anterior or posterior bands wider than or almost as wide as discal infuscation (Fig. 5C); elytral disc of many specimens with infuscation reduced to numerous lines of spots (Fig. 5C); metacoxal processes with apical spine very long (Figs. 22I, J) ...(*D. lapponicus*) ..... 13
- 12' Pronotum more narrowly margined with yellow, anterior and posterior bands much narrower than discal infuscation (Fig. 5D); elytral disc piceous to black (Fig. 5D); metacoxal processes of various lengths (Figs. 22K-N) .....14
- 13 (12) Pronotum with quadrangular infuscation (Fig. 5C); distributed in northern Europe to USSR (Fig. 47).....  
.....*D. lapponicus lapponicus* Gyllenhal, p. 486
- 13' Pronotum with infuscation greatly reduced, almost linear, in shape of printer's bracket, opening posteriorly; distributed in Italian Alps (Fig. 47).....  
.....*D. lapponicus disjunctus* Camerano, p. 490
- 14 (12') Metacoxal process with apical spine very long (Figs. 22K N)....16
- 14' Metacoxal process with apical spine shorter (Figs. 22F-H) .....15
- 15 (14') Eye enclosed dorsally by narrow yellow band, or, some specimens with band narrowly broken near inner posterior margin of eye; pterothoracic and abdominal sterna testaceous to pale rufous, basal margins of sterna testaceous to pale rufous, basal margins of sterna I to III very narrowly infusate in some specimens (Fig. 11D); male with apex of median lobe not sinuate in dorsal view (Fig. 18D) .....

- .....*D. circumcinctus* Ahrens, p. 477
- 15' Eye not enclosed dorsally by narrow yellow band, some specimens with inner margin margined with yellow or red; pterothoracic sterna with at least metasternum medially infuscate (Fig. 12B), abdominal sterna variable in colour pattern; male with apex of median lobe sinuate in dorsal view (Fig. 19C) .....*D. dauricus* Gebler, p. 483
- 16 (14) Abdominal sterna with broad fasciae (Fig. 13A left, D)..17
- 16' Abdominal sterna without, or with narrow fasciae (Fig. 13A right, B,C) .....19
- 17 (16) Distributed in Europe, Great Britain, southern Scandinavia and northern Africa (Fig. 48); male with protarsal claw about 0.50 length of protarsomere V; male with knob of median lobe not spatulate in lateral view (Fig. 20A) .....*D. circumflexus* Fabricius (in part), p. 490
- 17' Distributed from central USSR eastward (Figs. 49, 51); male protarsal claw about 0.67 length of protarsomere V; male with median lobe in lateral view spatulate or not (Figs. 20B, D) .....18
- 18 (17') Distributed in Peoples Republic of China (Fig. 51); male with knob of median lobe spatulate in lateral view (Fig. 20D).....*D. sinensis* Feng, p. 493
- 18' Distributed in central USSR, Afghanistan and Kashmir (Fig. 49); male with knob of median lobe not spatulate in ateral view (Fig. 20B).....*D. thianshanicus* Gschwendtner, p. 493
- 19 (16') Distributed in western Palearctic region (Fig. 48) .....*D. circumflexus* Fabricius (in part), p. 490
- 19' Distributed in central and eastern Palearctic region (Figs. 49, 50) .....20
- 20 (19') Head with chevron extended to antero-lateral margin; male with median lobe in dorsal view with pre-apical portion narrow (Fig. 20C); distributed in far eastern USSR (Fig. 50)...*D. latro* Sharp, p. 494
- 20' Head with chevron not extended to antero-lateral margin; male with median lobe in dorsal view with pre-apical portion broader (Fig. 20B); distributed in central USSR, Afghanistan and Kashmir (Fig. 49) .....*D. thianshanicus* Gschwendtner, p. 493

## Species Treatments

*Dytiscus verticalis* Say, 1823  
Figs. 1A, 7A, 14A, 21A, 24, and 52

*Dytiscus verticalis* Say, 1823:92 (Type area- not stated, but presumably from eastern United States. Type specimens probably lost, see below). -Zimmermann, 1920:255. -Hatch, 1929:226. -Wallis, 1950:51. -Wallis and Larson, 1973:110 -Larson, 1975:396.

*Derivation of specific epithet.*— Unclear but probably derived from Latin, meaning at the vertex, directly overhead or upright, possibly referring to the chevron on the vertex of the head.

*Notes about type material.*— As with most of the typical material of Thomas Say, original specimens are probably lost (Lindroth and Freitag 1969).

However, Say's original description is sufficiently diagnostic to indicate that this is indeed the taxon to which he was referring. Therefore a neotype is not needed.

*Diagnostic combination.*— Large size, sub-apical transverse fascia of elytron of most specimens (Fig. 1A), infusate venter, and pronotum with broad yellow lateral margins only, permit easy recognition of adults of this Nearctic species.

*Description.*— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 1A; coloration of pterothoracic sterna and abdominal terga in Fig. 7A; median lobe of male in Fig. 14A; and metacoxal processes in Fig. 21A.

*Variation.*— Adults are relatively uniform in coloration. Pronota and elytra of a very few specimens have a dark greenish cast. The sub-apical transverse fascia of the elytron varies in width and distinctness and is absent from a few specimens. Pronota of a few specimens have the anterior and posterior margins marked with yellow bands, less than 10% of width of lateral bands. Some other specimens have piceous anterior and posterior margins of the pronotum.

*Natural history.*— This species seems to be most common in ponds in the eastern deciduous forest and adjacent areas. Young (1966) discussed methods for laboratory rearing of *D. verticalis*. Formanowicz and Brodie (1981) present information about pupation.

Brodie and Formanowicz (1981, 1983), Brodie *et al.* (1978), Formanowicz (1982, 1986, 1987), Leclair *et al.* (1986) and Formanowicz and Bobka (1989) analyzed aspects of predation of larval *D. verticalis* on amphibian larvae of *Rana* spp. (Ranidae), *Hyla* spp. (Hylidae), *Bufo* spp. (Bufonidae), *Ambystoma* spp. (Ambystomidae) and *Notophthalmus* sp. (Salamandridae). In general, larvae of *D. verticalis* are avid predators of immature amphibians and consume several prey daily.

Data on labels are interpreted as evidence for an autumnal dispersal after emergence from the pupal stage (Table 4). Autumnal dispersal could take place soon after emergence from the pupa, as a teneral specimen from Ann Arbor, Michigan, was taken at a porch light in July (Tables 4 and 5). Other data suggestive for an autumnal dispersal flight are listed in Table 5. No information is available about overwintering sites, *i.e.*, in water or on land, but adults of *D. verticalis* appear to have a vernal dispersal (Table 5) which could be associated with movement to temporary vernal ponds as well as permanent ponds where larval development occurs (see above), although label records for definitely temporary ponds are scarce (Ontario, near Huntsville 31.v.72 and 7.vi.66 [2 ROMC]).

*Distribution.* (Fig. 24).— This is a species of eastern North America which ranges as far west as western Manitoba and western Wisconsin and as far south as North Carolina with one dubious unmapped record from Homestead, Florida (1 MCZC). Records of this species from the State of California [Stan. U. 19.iv. - (2 CASC) and a state record only (1 ICCM)] are probably in error. The majority of records are from Connecticut, Massachusetts and New York.

*Chorological relationships.*— *Dytiscus verticalis* is broadly sympatric with all other Nearctic species which occur in eastern North America except the more northerly *D. dauricus* and *D. alaskanus*.

*Phylogenetic relationships.*— The basal segment of the labial palpus of third instar larvae of *D. verticalis* lacks the false segmentation of every other known third stage larva of *Dytiscus* (Wilson 1923, Fig. 37 and Roughley, unpublished data) and in this state they are similar to third stage larvae of *Hyderodes shuckardi* Hope (Watts 1964, Fig. 16). Because of the distribution of this character state, I suggest that *D. verticalis* is the sister group to the remainder of *Dytiscus* (Fig. 52).

*Material examined.*— A total of 993 adult specimens were examined of which 349 are males, 420 are females, and for 224 specimens sex was not determined.

*Dytiscus harrisii* Kirby, 1837

Figs. 1B, 7B, 14B, 21B, 23A, 25, and 52

*Dytiscus harrisii* Kirby, 1837:76 (Type area- "taken in the Journey from New York to Cumberland-house." Holotype- see Larson 1975:397.). -Zimmermann, 1920:242, 248. -Hatch, 1929:277. -Hatch, 1953:238. -Gordon and Post, 1965:25. -Wallis and Larson 1973:110. -Larson, 1975:397.

*Derivation of specific epithet.*— Kirby named this species in honour of T.W. Harris, "...a very eminent American entomologist."

*Diagnostic combination.*— Bisinuate anterior margin of clypeus, large size, and combination of distinctive dorsal and ventral colour pattern (Figs. 1B, 7B, and 23A) allow easy recognition of adults of this species.

*Description.*— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters of adult males and females are given in Table 3. Dorsal view of the body is shown in Fig. 1B; coloration of pterothoracic sterna and abdominal terga in Fig. 7B; median lobe of male in Fig. 14B; and metacoxal processes in Fig. 21B.

*Variation.*— Adults are relatively uniform in coloration. Pronota and elytra of a very few specimens have a dark green cast. Colour of legs varies, with the posterior faces of the pro- and mesofemora testaceous in some specimens, rather than the usual piceous to black. This difference is not completely correlated with geographic locality of the specimen but is more common in eastern North America. The subapical transverse fascia of the elytron varies in width and distinctness but is present in all specimens examined.

Larson (1975) commented about the small size of specimens from Alberta and Northwest Territories compared to specimens from Ontario and Wisconsin. A similar difference was found by me, and is interpreted as indicative of sampling bias (see Measurements). Differences in length can be explained by a greater size range for adult *D. harrisii* in northwestern North America with smaller specimens being more often captured; whereas, in eastern North America the size range is less and therefore the adult stage appears to be larger within this area.

*Natural history.*— I have evidence from western Canada that larval development takes place in or near running water (Roughley, in prep.). The remainder of the life cycle can be inferred from information on labels of adult specimens examined. Adults probably overwinter in relatively permanent water bodies [Vermont, Burlington, 22.ii.49, taken through fishing hole in ice, L. Champlain, (1, UVCC)]. Depending on local climatic and other factors, larval development is completed by June or July as indicated by occurrence of teneral

adult specimens (Table 4), and mature, field-collected pupae [Alberta, Kneehills Creek near Acme, pupa coll'd. 23.vi.80, adult emg'd. 6.vii.80, (1, JBWM); British Columbia 1 km N Golden, prepupa coll'd. 21.vi.80, adult emg'd. 10.vii.80 (1, JBWM)]. The adult teneral specimen from southern Alberta, 3.ix.61, reported by Larson (1975:398) probably represents an exceptional situation. Following shortly after adult emergence is a dispersal flight (Table 5), presumably to overwintering sites but possibly to localities where feeding takes place before overwintering begins. During these dispersal flights, specimens are collected in non-typical habitats such as beach drift, and swimming pools (Table 5).

*Distribution (Fig. 25).*— The range of this species is transcontinental in the Nearctic region, from Newfoundland to Alaska. The northern limit of distribution is probably coincident with treeline and the southern limit appears to be the latitude of southern Pennsylvania, central Nebraska and northern Washington. Most specimens are from states and provinces in the vicinity of the Great Lakes.

*Chorological relationships.*— *Dytiscus harrisii* is sympatric with all other Nearctic species of *Dytiscus* except *D. habilis* and *D. carolinus*.

*Phylogenetic relationships.*— This species is probably related to a species complex which includes *D. habilis*, *D. hybridus*, and *D. marginicollis* (Fig. 52).

*Material examined.*— A total of 571 adult specimens was examined of which 270 are males, 285 are females, and for 14 specimens sex was not determined.

*Dytiscus hybridus* Aubé, 1838  
Figs. 1D, 7C, 14C, 21C, 26, and 52

*Dytiscus hybridus* Aubé, 1838:116 (Type area - "États Unis d'Amérique." Type not seen.). - Zimmermann, 1920:248. - Hatch 1929:226. - Hatch 1933:11. - Wallis 1950:51. - Gordon and Post 1965:24. - Wallis and Larson 1973:110. - Larson 1975:398.

*Leionotus compar* Melsheimer, 1844:26 (Type area - "Pennsylvania and Massachusetts." Type not seen.). - Zimmermann 1920:248.

*Derivation of specific epithet.*— From the Latin hybrida meaning a hybrid or an indication of hybridization, presumably because, to Aubé, adults of this species demonstrated a mixture of the characteristics of other species.

*Notes about type material.*— I searched for, but was unable to find, any type material within the R. Oberthür collection in MNHN.

*Diagnostic combination.*— Adults of *D. hybridus* are distinguished from adults of other species of *Dytiscus* with piceous to black venters, by smaller size, non-explanate pronotal margins, and presence of wide yellow margins laterally only on pronotum. Females not sulcate. Males with mesotarsomeres I to III ventrally with longitudinal glabrous area.

*Description.*— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters of adult males and females are given in Table 3. Dorsal view of the body is shown in Fig. 1D; coloration of pterothoracic and abdominal sterna in Fig. 7C; median lobe of male in Fig. 14C; and metacoxal processes in Fig. 21C.

*Variation.*— The most conspicuous variation of adult *D. hybridus* is in coloration of the pronotal margin. The most common condition is absence of posterior pronotal yellow band but with a very narrow anterior band. Some specimens have both the anterior and posterior bands obliterated and still others have both of these bands present and distinct. In examples of the latter, the

anterior band is wider than the posterior band, and both are less than 0.33 width of a lateral band.

Other than pronotal bands, adults of this species are quite uniform in colour and in structural features. Most other differences in colour (*e.g.* piceous rather than black venter) are probably due to age of specimens when collected (*e.g.* fully sclerotized versus teneral). Compared to most other species of *Dytiscus*, *D. hybridus* occupies a smaller geographic range and is structurally more homogeneous.

*Natural history.*— Apparently this is a species which prefers mature ponds within the eastern deciduous forests of North America. Collection of an adult female in December at Ithaca, New York could be interpreted as evidence that the adult stage overwinters in water. However, specimens have been collected in flight in Pennsylvania in December and in Illinois in January, and may indicate dispersal from any over-wintering habitat. Teneral specimens from the more southerly portions of the range were taken in June and July (Table 4). Specimen data indicative of flight period are inconclusive (Table 5); adults may have only an extended late-season flight (July to January) depending on geographic location, or a late season flight (July to September) and a very early season flight (December to January).

*Distribution* (Fig. 26).— This strictly Nearctic species appears to be common only east of the 100th meridian. Scattered localities, perhaps indicating range expansion (Larson 1975:398), extend the range to Oregon and northward into Alberta. The southern limit is represented by specimens from Missouri, Tennessee, and South Carolina. The hiatus in locality information in the eastern USA, which coincides with the eastern mountain chains, could be indicative of less collecting effort, lack of suitable habitat within the area, or of avoidance of montane habitats by adults of this species. The more north-central and north-eastern "limits" are probably artificial and due to insufficient collecting.

*Chorological relationships.*— Within the *D. hybridus* species-group, *D. hybridus* is broadly sympatric with *D. harrisii* only.

*Phylogenetic relationships.*— Adults of this species exhibit a high number of plesiotypic character states when compared to other members of the *D. hybridus* species-group. As such, of the four extant taxa, it is probably the most similar to the hypothetical ancestor of this clade.

*Material examined.*— A total of 1636 adult specimens were examined, of which 852 are males, 778 females, and 6 are of undetermined sex.

### *Dytiscus marginicollis* LeConte, 1845

Figs. 7D, 14D, 21D, 27, and 52

*Dytiscus marginicollis* LeConte 1845:209, Fig. 10, plate XVIII (Type locality -"in flumine Missouri". Holotype female in LeConte collection of MCZC labelled as follows: [green circular label] Type 6091 [red label] *D. marginicollis* Lec., albionicus Motsch.). - Zimmermann 1920:252 (*ex parte*). -Hatch 1929:226, 1933:11. -Leech 1941:290, 1948:414. -La Rivers 1951:404. -Hatch 1953:238. -Leech and Chandler 1956:323. -Anderson 1962:73. -Larson 1975:398.

*Dytiscus albionicus* Motschulsky 1859:166 (Type locality - Fort Ross near San Francisco, California, U.S.A.) (Holotype female in ZILR labelled as follows: 81.; *Dytiscus albionicus* Motsch.; *D. marginicollis* Lec., Zaicev det.; HOLOTYPE, *Dytiscus albionicus*, Motschulsky 1859 examined R.E. Roughley). -Zimmermann 1920:244.

*Dytiscus anxius*; Gemminger and Harold 1868:461, *nec* Mannerheim 1843:218.

*Dytiscus anxius* var. *albionicus*; Gemminger and Harold 1868:461. -Zimmermann 1920:244; *nec* Mannerheim 1843:218, *nec* Motschulsky 1859:166.

*Dytiscus vexatus*; Hatch 1929:226, *nec* Sharp 1882:643.

*Derivation of specific epithet.*— From Latin, *marginare*, to enclose within a border, and *collum* meaning neck, in reference to the yellow margins of the pronotum.

*Notes about type material.*— My interpretation of the placement of *D. albionicus* Motschulsky differs from that of Larson (1975:401), and other authors who have placed this name as a junior synonym of *D. circumcinctus*. Reassignment is based on absence of *D. circumcinctus* from California, USA, from which Motschulsky described *D. albionicus*. Also, the type of *D. albionicus* was examined and it is a typical female of *D. marginicollis*.

*Diagnostic combination.*— Distinctive pronotal and ventral coloration (Fig. 7D) separate adults of this Nearctic species from those of all other species except *D. habilis*. Adult males of *D. marginicollis* are distinguished from males of *D. habilis* by mid-ventral glabrous areas on mesotarsomeres II and III. Males and females of *D. marginicollis* also have an increased area of the pronotal disc infuscate and the posterior margin of this infuscation is sinuate. Adults of *D. marginicollis* are longer than those of *D. habilis* (Table 2). Females of both taxa are not sulcate. The range of *D. habilis* is south of that of *D. marginicollis* (Fig. 27; cf. Fig. 28).

*Description.*— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is not shown; coloration of pterothoracic sterna and abdominal terga is shown in Fig. 7D; median lobe of male in Fig. 14D; and metacoxal processes in Fig. 21D.

*Taxonomic notes.*— Leech (1948) noted that two male specimens which he examined from Baja California, México, might represent a distinct subspecies as they are more parallel-sided than other specimens. I have seen these specimens and judge them to be within the range of variation shown by more northern specimens.

*Variation.*— One of the most consistent character states shown by adult specimens of *D. marginicollis* is sinuation of anterior and posterior margins of the discal infuscation of the pronotum. This state has permitted rapid and efficient sorting of members of this taxon. In contrast, there is extreme variation in colour of the scutellum and, to a lesser extent, of legs. The scutellum varies from completely yellow to completely piceous in most population samples. Leg colour varies similarly, and these two states are not completely correlated, although there are general trends to extremes of both states in some specimens. Some specimens have elytral disc with obsolete irrorations. Post-mortem changes can discolor ventral and dorsal colour patterns. These are usually easily overcome by proper cleaning of specimens. Other structural and colour characters are relatively uniform.

*Natural history.*— Most habitats where I have collected adults of this species are characterized by high salinity, typical of ponds in grassland areas, and stands of *Scirpus* species. Larson (1975:399) noted an affinity for what were presumed to be permanent prairie sloughs in conjunction with *Typha* and *Juncus*.

Adults and larvae of *D. marginicollis* are able to use hot springs as habitats. Brues (1928: 152, 153, 176) recorded adults from a group of springs near Battle Mountain, Nevada in which the temperature was 30°C. Brues (1932:272) recorded a large larva of *Dytiscus*, which is presumably that of *D. marginicollis*, from a cooler (17°C) spring in Yellowstone National Park, Wyoming.

Holomuzki (1986) records *D. marginicollis* at elevations between 1500 and 2500 m in east central Arizona where it coexists with tiger salamanders. In this region, *D. dauricus* occurs with the same salamander but at higher elevations (2500+ m). The record of a larval *Dytiscus* killing a young garter snake (Drummond and Wolfe 1981) is almost certainly for *D. marginicollis* (Roughley unpubl.) although garter snakes are not likely normal prey for them.

Flight records are available for many months of the year, with July predominating (Table 5). Dispersal could follow shortly after emergence from pupae, as records of teneral specimens range from May to August (Table 4).

*Distribution* (Fig. 27).— The range of this species is perhaps significantly, if broadly, described as west of that of *D. hybridus* and north of that of *D. habilis*. The eastern-most record is from Aweme, Manitoba, Canada, and the southern-most from San Dimas, Durango, México. Records of this taxon from Alaska (e.g. Hatch 1929, Leech 1948, Larson 1975) are suspect, and could stem from the inclusion of *D. marginicollis* as a junior synonym of *D. anxius*, the type locality of which is Sitka, or from Hatch's inclusion of *D. vexatus* as a junior synonym of *D. marginicollis*. However, further collecting could well extend the range of this species northward along the British Columbia coast and perhaps into southernmost Alaska. The northernmost records of adult specimens are from Calgary and Lethbridge, Alberta, Canada, although I have seen mature larvae from George Lake, near Dunstable, Alberta. The record for the state of Durango, México, mentioned above, may seem inconsistent except that I have many larval records from Baja California, México (and none for *D. habilis*, Roughley, in prep.) and the Durango specimen may represent dispersal from Baja California del Sur.

*Chorological relationships*.— The exclusively western North American distribution of *D. marginicollis* excludes sympatry with *D. carolinus* and *D. verticalis*. It is only narrowly sympatric or parapatric with *D. hybridus* and *D. habilis*.

*Phylogenetic relationships*.— Within the *D. hybridus* assemblage, adults of *D. marginicollis* are most similar in colour pattern to those of *D. habilis* and these two species are more similar to *D. harrisii* than to *D. hybridus*. Despite these similarities, *D. marginicollis* is probably the sister species to *D. hybridus* based on common possession of glabrous areas on the male mesotarsomeres (Table 3 and Fig. 52).

*Material examined*.— A total of 972 adult specimens was examined, of which 443 are male, 526 female, and sex was not determined for 3 specimens.

#### *Dytiscus habilis* Say, 1834

Figs. 1C, 8A, 15A, 21E, 28, and 52

*Dytiscus habilis* Say 1834:441 (Type area "...in the river beyond Vera Cruz...", México. Type probably lost.). -Zimmermann 1920:248. -Darlington 1938:84. -Wallis 1950:51.

*Derivation of specific epithet*.— This name is derived from the Latin, *habilis*, meaning apt, fit, suitable (Brown, 1956).

*Notes about type material*.— Say's types are probably lost (see equivalent section under *D. verticalis*). Because Say's original description agrees well with the present concept of this taxon (specimens within the LeConte collection, MCZC, belong to this taxon), and considering that *D. habilis* is the only species which is widespread in México, a neotype is not required.

*Diagnostic combination*.— See discussion under equivalent section in treatment of *D. marginicollis*.

*Description.*— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 1C; coloration of pterothoracic sterna and abdominal terga in Fig. 8A; median lobe of male in Fig. 15A; and metacoxal processes in Fig. 21E.

*Variation.*— Most of the types of variation discussed under *D. marginicollis* apply equally well to *D. habilis*.

*Natural history.*— Nothing has been published concerning natural history of this species. Available flight records are for April and October in Chihuahua, México, and June in Arizona, USA (Table 5). From limited specimen label data it appears that specimens are taken at increasing elevations further south in the range. For instance, in Arizona [Cochise Co., SW Res. Stn., 5 mi S Portal (FNYC, USNM)] specimens were taken at 1645 m, whereas specimens from northern México [Chihuahua, 5.1 km n Colonia Garcia, 23.vii.79 (1 JBWM)] were taken at 2010 m and at 2560 m in Guatemala (Huehuetenango, 7 mi N Santa Eulalia on road to San Mateo Ixtatán, 5.ii.65 (4 CASC)]. Other label information is scarce but the specimen mentioned above was taken at the margin of a creek, and another Mexican specimen [Chiapas, San Cristóbal de las Casas, 6.vii.64 (1 CASC)] was taken in a habitat characterized as "pond and spring".

*Distribution* (Fig. 28).— From southwestern Arizona, southeastern New Mexico, and southwestern Texas, USA, this species ranges southward to Guatemala.

*Chorological relationships.*— Along the northern edge of its range, *D. habilis* is either narrowly sympatric or allopatric with *D. marginicollis*. It is not sympatric with, nor does its range closely approach, that of any other species of *Dytiscus*.

*Phylogenetic relationships.*— The similarity to specimens of *D. marginicollis* was noted in discussion of that species. *Dytiscus habilis* is interpreted as representative of sister lineage to that of *D. hybridus* plus *D. marginicollis* (Fig. 52).

*Material examined.*— A total of 240 adult specimens was examined, of which 148 are males, 90 females, and 2 are of undetermined sex.

- Dytiscus punctulatus* ab. *maurus* Schaufuss 1882:clxxiii (Type locality -Dresden in Dresden, West Germany. Type not seen.). -Zimmermann 1920:254. -Guignot 1932:709. -Zimmermann and Gschwendtner 1938:38. -F. Balfour-Browne 1950:268. -Zaitsev 1953:324. -Guignot 1961:857.
- Dytiscus punctulatus* var. *expectata* Peyerimhoff 1905:229 (Holotype female from Algeria in MNHN labelled as follows: Lac de Mouzaïa, 15 Juin 1905; v. *expectatus* type unique; HOLOTYPE, *Dytiscus punctulatus* var. *expectata* Peyerimhoff, examined R.E. Roughley 1981.).
- Dytiscus punctulatus* var. *expectatus* Peyerimhoff. **Justified emendation.** -Zimmermann 1920:254. -Guignot 1932:709. -Zimmermann and Gschwendtner 1938:38. -Guignot 1947a:242. -F. Balfour-Browne 1950:268. -Zaitsev 1953:324. Guignot 1961:858. -Schaefflein 1971:87. -Franciscolo 1979:662.
- Dytiscus punctulatus* var. *laevis* Engert 1911:19 (Type locality-Corfu, Greece. Type not seen.). -Zimmermann 1920:254. -Zimmermann and Gschwendtner 1938:38. -Guignot 1961:858.
- Derivation of specific epithet.**— From Latin, in reference to the short sulci or grooves on the female elytra.
- Diagnostic combination.**— European distribution, infusate venter (Fig. 8B) and pronotum with lateral yellow margins only (Fig. 2A) easily distinguish adults of this taxon.
- Description.**— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 2A; coloration of pterothoracic sterna and abdominal sterna in Fig. 8B; median lobe of male in Fig. 15B; and metacoxal processes in Fig. 21F.
- Variation.**— Guignot (1961:857) suggested that the completely piceous colour of specimens of *D. semisulcatus* which Schaufuss described as ab. *maurus* is the result of post-mortem changes. Pronotal colour pattern (Fig. 2A) is quite uniform in specimens that I have seen. Only very few specimens have the anterior margin of pronotum narrowly reddish or yellowish. Most specimens have the legs completely infusate, except for anterior faces of protibia and protarsus of both sexes, and the femoral-tibial juncture of the hind two pairs of legs is marked by a rufous spot. The venter is piceous to black. Throughout most of its range, adult females exhibit sulcate elytra. Only in Palearctic Africa do non-sulcate females make up a significant proportion of population samples.
- Natural history.**— *Dytiscus semisulcatus* is the only species of *Dytiscus* known to overwinter in the larval stage. Blunck (1916a) discussed the life cycle

of this species in detail, indicating pupation in May. This is in contradistinction to the implication by F. Balfour-Browne (1950:270) that the life cycle in England is bimodal. F. Balfour-Browne (1950) provides other natural history notes, as does Guignot (1932), and the former author records the majority of teneral specimens for July, August and September. It is apparently a species of strictly fresh-water habitats.

*Distribution* (Fig. 29).— This species ranges throughout Europe except in the north, but also occurs in northern Africa (Guignot 1961). The eastern-most record is from Turkestan, Kazakh SSSR. It occurs northward as far as southern Sweden based on locality information from specimens examined. Apparently it has been introduced into New Zealand (Ordish 1966).

*Chorological relationships*.— *Dytiscus semisulcatus* is broadly sympatric with most other European species of *Dytiscus*. Available distribution records suggest only narrow sympatry with *D. mutinensis* and *D. lapponicus*.

*Phylogenetic relationships*.— I interpret this taxon, based on adult characters, to be the most plesiotypic of the extant species of *Dytiscus* of which females have sulcate elytra (Fig 52).

*Material examined*.— A total of 469 specimens was examined of which 242 are males and 217 are females.

*Dytiscus sharpi* Wehncke, 1875  
Figs. 2B, 8C, 15C, 21G, 30, and 52

*Dytiscus sharpi* Wehncke 1875:500 (Type area - "Japan". Lectotype male designated here from the Wehncke collection, MNHN, labelled as follows: LECTOTYPE; SYNTYPE; Japonia [yellow label, black edging]; Thoiry; sharpi mihi.). -Zimmermann 1920:254. - Zimmermann and Gschwendtner 1938:40 -Zaitsev 1953:325.

*Dytiscus validus* Régimbart 1899:311 (Type locality - "Nagahama, Japan". Lectotype male designated here in the Régimbart collection, MNHN, labelled as follows: LECTOTYPE; SYNTYPE; Nagahama, July 1886, Leech; LECTOTYPE, *Dytiscus validus* Régimbart R.E. Roughley.). -Zimmermann 1920:254. -Zaitsev 1953:325. **NEW SYNONYMY.**

*Derivation of specific epithet*.— Not specifically stated by Wehncke, but obviously named in honour of the British entomologist, David Sharp. Sharp had begun to accumulate the specimens for his 1882 monograph as early as 1875 according to Severin (1892) and would have been well known to Wehncke.

*Diagnostic combination*.— Adults of this species are most similar to those of *D. semisulcatus*. These are the only two Palearctic species with adults with yellow borders only on lateral margins of pronotum and infusate venter. This species is found only in the eastern part of the Palearctic Region. In addition to differences in body shape, specimens of these taxa are easily separated on the basis of tarsal character states presented in the key.

*Description*.— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 2B; coloration or pterothoracic sterna and abdominal terga in Fig. 8C; median lobe of male in Fig. 15C; and metacoxal processes in Fig. 21G.

*Variation*.— Too few specimens were seen to identify geographic patterns of variation. Few specimens have the anterior margin of the pronotum narrowly reddish. All females I have seen have sulcate elytra, but the female syntype from Wehncke's collection is sulcate basally only, the grooves are only about half as long as in other specimens of the same sex. Some specimens (teneral?) have legs completely brownish-yellow and abdominal terga indistinctly maculate (Fig. 8C). Most specimens have legs and venter black.

*Natural history*.— I can find nothing published about the natural history of this species, nor does the scanty label data supply any information.

*Distribution* (Fig. 30).— I have seen records for the People's Republic of China and Japan only. This species is expected to occur also in the extreme southeastern corner of the USSR.

*Chorological relationships*.— *Dytiscus sharpi* is broadly sympatric only with *D. delictus*, *D. dauricus* and *D. marginalis czerskii*.

*Phylogenetic relationships*.— This taxon and *D. semisulcatus* form the sister group to a Nearctic complex of species which includes *D. fasciventris*, *D. carolinus* and *D. hatchi* (Fig. 52).

*Material examined*.— A total of 21 specimens was examined of which 10 are males and 11 are females.

*Dytiscus carolinus* Aubé, 1838  
Figs. 2C, 8D, 15D, 21H, 31, and 52

*Dytiscus carolinus* Aubé 1838:120 (Type area—"États Unis d'Amérique". Type not seen.). **NEW STATUS.**

*Dytiscus fasciventris*; *auctorum, nec* Say 1824:270. -LeConte 1859:177 (*ex parte*). -Crotch 1873:408 (*ex parte*). Wickham 1895 (*ex parte*). -Roberts 1905:106 (*ex parte*). Blatchley 1910:231 (*ex parte*). -Zimmermann 1919:233 (*ex parte*). -Zimmermann 1920:248 (*ex parte*). -Hatch 1929:226 (*ex parte*). -Wallis 1950:51 (*ex parte*). -Hatch 1953:237 (*ex parte*). -Michael and Matta 1977:41.

*Dytiscus* sp.; Young 1954:26.

? *Dytiscus fasciventris*; -Folkerts 1978:346.

*Derivation of specific epithet*.— Not stated by Aubé, but presumably referring to the type area which is presumably the east coast of the USA in the region occupied by the states of North and South Carolina.

*Notes about type material*. - I acknowledge the help of Dr. F.N. Young, Bloomington, Indiana who first pointed out the validity of this taxon. I have not seen Aubé's type(s), but the original description makes it clear that this is indeed the taxon to which he was referring.

*Diagnostic combination*.— Characters presented in the key, and the more southern distribution provide a reliable distinction among adults of *D. fasciventris* and *D. carolinus*.

*Description*.— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 2C; coloration of pterothoracic sterna and abdominal terga in Fig. 8D; median lobe of male in Fig. 15D; and metacoxal processes in Fig. 21H; structure of protarsi in Fig. 23D and of mesotarsi in Fig. 23F.

*Taxonomic notes*.— See equivalent section in the treatment of *D. fasciventris*.

*Variation*.— See notes under variation in the treatment of *D. fasciventris*.

*Natural history*.— Dr. J.F. Matta, Old Dominion University, Norfolk, Virginia, USA, has provided unpublished collecting notes for this species in Virginia. Adults were collected at sites in which the dominant aquatic vegetation was: 1. *Ludwigia palustris* and *Lemna geyseri*; 2. *Utricularia* sp.; and 3, no vegetation. Proportion of surface of ponds covered by vegetation varied from zero to complete. Each site was characterized by a large amount of detritus. Sites varied from relatively unshaded to ponds under a closed canopy.

One teneral adult male specimen (Table 4) was seen and bears the additional information: larva coll. 21.iv.73, pupa 2.v.73, ad. emerged 11.v.73. Flight

records (Table 5) are two each for April and June, and one each for July and October.

*Distribution* (Fig. 31).— Distributed in a broad U-shape, from southern New England, south along the Atlantic and Gulf Coast to southern Georgia, and north along the Mississippi River drainage system to southern Michigan and extreme southeastern Wisconsin, USA. As for *D. hybridus*, absence of records for *D. carolinus* in eastern mountains is notable.

*Chorological relationships*.— *Dytiscus carolinus* seems most broadly sympatric with *D. verticalis* and *D. hybridus*. Zones of parapatry with *D. fasciventris* are noted under variation and taxonomic notes in the treatment of that species.

*Phylogenetic relationships*.— Closely related to *D. fasciventris* and *D. hatchi*, *D. carolinus* is the most plesiotypic of the Nearctic species females of which have sulcate elytra (Fig. 52).

*Material examined*.— A total of 91 specimens was examined of which 35 are males and 56 are females.

*Dytiscus fasciventris* Say, 1824

Figs. 2D, 9A, 16A, 21I, 32, and 52

*Dytiscus fasciventris* Say 1824:270 (Type area—"Lake Superior". Type probably lost). - Zimmermann 1920:248 (*ex parte*). - Hatch 1929:226 (*ex parte*). - Wallis 1950:51 (*ex parte*). - Hatch 1953:237 (*ex parte*). - Wallis and Larson 1973:110. - Larson 1975:399.

*Derivation of specific epithet*.— From the Latin fascia, band or stripe, and venter, belly (Brown 1956), in reference to the alternating black and yellow fasciae on the abdomen of adult specimens.

*Notes about type material*.— Say's type is probably lost (Larson 1975:400). Although the separation of *D. carolinus* would seem to require a type designation for one of these taxa, I hesitate to do so until it can be determined convincingly that type material of *D. carolinus* is no longer extant. I am confident of assignment of these two names because of the differing type areas for these taxa.

*Diagnostic combination*.— Characters presented in the key and mentioned below in the section on variation should be adequate to distinguish among specimens of the three closely related species: *D. fasciventris*, *D. hatchi* and *D. carolinus*.

*Description*.— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 2D; coloration of pterothoracic sterna and abdominal terga in Fig. 9A; median lobe of male in Fig. 16A; and metacoxal processes in Fig. 21I.

*Taxonomic notes*.— Specimens of *D. fasciventris* have long been confused with those of *D. carolinus*, but I recognize two species. Possible introgression between *D. fasciventris* and *D. carolinus* in eastern North America, and between *D. fasciventris* and *D. hatchi* in western North America (see below) is problematic in that if all three are reproductively isolated but closely related taxa, then one would expect character displacement rather than character convergence within areas of sympatry. Despite limited convergence, I retain specific level status for each of these taxa because: 1, introgression has not been conclusively demonstrated; and 2, convergence is limited to a few characters only among *D. fasciventris* and *D. carolinus*. I do not treat *D. carolinus* and *D. fasciventris* as subspecies because: 1, the area where maximum similarity

apparently occurs is north of the known range of *D. carolinus*; 2, there is no convergence in at least two characters (colour of metacoxal plates and shape of median lobe); and 3, difference in amount of character convergence among samples of specimens from Michigan and from the north-eastern United States.

No evidence suggests that introgression occurs now. In fact, variation in degree of character convergence is suggestive of an alternative hypothesis. Much of the apparent similarity could be derived from compression, fragmentation and broad overlap of ranges which would have been necessary adjustments to, for instance, the Wisconsin glacial epoch. Thus the apparent convergence could be indicative of Wisconsin rather than Holocene introgression. More extensive collections of specimens from the zones of parapatry and sympatry, and attempts to cross these putative specifically distinct taxa in laboratory and field situations will determine their ultimate taxonomic fate.

The major consistent differences among adult specimens of *D. fasciventris* and *D. carolinus* are given in the key to species. Other differences are length and width (Table 2), differences in form of the apex of the median lobe (compare Figs. 15D and 16A), and leg colour (generally darker in *D. carolinus*).

Wallis (1950:51) listed a number of subtle differences among specimens of *D. fasciventris* and *D. hatchi*, other than those used in the key. These are: 1, males of *D. hatchi* with elytra more distinctly punctate basally; 2, median lobe of male *D. hatchi* more linear than that of males of *D. fasciventris*; 3, infuscate markings of abdominal sterna touching the inter-sternal suture in *D. fasciventris*, as compared to isolated central blotches in *D. hatchi*; and 4, broader anterior and posterior bands of yellow of pronotum on specimens of *D. hatchi*.

*Variation*.— Specimens from central and northern portions of the range exhibit little variation. However, specimens occurring sympatrically with *D. carolinus* exhibit limited convergence with that species, mainly with respect to coloration. In southern New England and adjacent areas of the USA, specimens of *D. fasciventris* are more extensively marked with reddish colour on the abdominal sterna and thus are more similar to north-eastern specimens of *D. carolinus*. As well, north-eastern specimens of *D. carolinus* are larger than more southern specimens, and therefore these two taxa are more similar in size in this region. Specimens from this area are recognized by yellow versus infuscate metacoxal plates, females with protarsal claws shorter or subequal versus longer than protarsomere V, and shape of the median lobe of males (see key).

The other major area of sympatry, notably in Michigan, is more problematic. Most specimens from Michigan and Wisconsin are easily assigned to one or other of the names on the basis of the characters listed above. However, a few females that I have assigned to *D. fasciventris* [Michigan, Cheboygan Co., Douglas Lake, 16.vii.1978 (JBWM)] have protarsal claws longer than protarsomere V, expanded infuscation on metasternal wings, and extensive areas of red colour on abdominal sterna. Other Michigan specimens show similar traits, especially with respect to length of female claws and sternal colour. Most of these specimens are from localities north of the known range of *D. carolinus*, but still within the potential dispersal range of this species. In Michigan, then, specimens from a few localities have character states indicative of limited introgression among *D. fasciventris* and *D. carolinus*.

A similar but less complex situation is indicated among specimens of *D. fasciventris* and *D. hatchi*. Pronota of eastern specimens of *D. fasciventris* lack or have very narrow anterior and posterior yellow margins. Specimens from Alberta and British Columbia have much wider anterior and posterior yellow

margins. In some examples, the anterior yellow margin is 0.2 of pronotal length (Wallis 1950:51). Thus, western specimens of *D. fasciventris* are more similar to *D. hatchi* in this character, although other characters are consistently different among these two taxa. Therefore, there is a possibility that introgression is occurring or has occurred among western populations of *D. fasciventris* and *D. hatchi*.

*Natural history.*— James (1961, 1970) and Larson (1975) provide natural history notes about this species in Ontario and Alberta, Canada, respectively. Adults probably reproduce quite early in the spring and are avid predators of early spring mosquitoes. James (1970) discusses parasitoids of pupae of *D. fasciventris*.

Flight records are roughly divisible into a vernal dispersal flight from April to late June, and a post-emergence flight from July to November (Table 5). All available records for teneral specimens are for the month of July (Table 4 and Larson 1975:400).

*Distribution.* (Fig. 32).— Transcontinental in North America, from the Maritime Provinces to Vancouver Island in Canada, this species extends southward to extreme southern Indiana, USA. The northern-most record is for Dawson City in Canada's Yukon Territory.

*Chorological relationships.*— Throughout its entire range, *D. fasciventris* is sympatric (at least narrowly so) with every other Nearctic species of *Dytiscus* except *D. habilis*.

*Phylogenetic relationships.*— *Dytiscus fasciventris* forms, in conjunction with *D. carolinus* and *D. hatchi*, a closely related assemblage of relatively recent origin (Fig. 52), judging by the relatively small amount of structural divergence of adults, evidence of possible introgression, and geographical replacement of these taxa with only narrow zones of sympatry.

*Material examined.*— A total of 1,257 specimens was examined of which 610 are males, 645 females, and sex was not determined for 2 specimens.

*Dytiscus hatchi* Wallis, 1950

Figs. 2E, 9B, 16B, 21J, 23C, 33, and 52

*Dytiscus hatchi* Wallis 1950:50 (Type locality - as below. Holotype male in CNIC, labelled as follows: Pond N. of Bethel, Washington, Apr. 21, 1940; holotype male *Dytiscus hatchi* Wallis; holotype *Dytiscus hatchi* Wallis No. 5880). -Hatch 1953:237. -Leech and Chandler 1956:323. -Larson 1975:400.

*Derivation of specific epithet.*— Wallis named this taxon in honour of Melville Hatch, the noted coleopterist.

*Diagnostic combination.*— Character states presented in the key and distribution, supplemented by characters mentioned in taxonomic notes under treatment of *D. fasciventris* allow accurate determination of adult specimens of *D. hatchi*.

*Description.*— Measurements for largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of the body is shown in Fig. 2E; coloration of pterothoracic sterna and abdominal terga in Fig. 9B; median lobe of male in Fig. 16B; and metacoxal processes in Fig. 21J; and mesotarsal structures in Fig. 23C.

*Taxonomic notes.*— See equivalent section in treatment of *D. fasciventris*.

*Variation.*— Important aspects of variation are discussed in section about variation in the treatment of *D. fasciventris*.

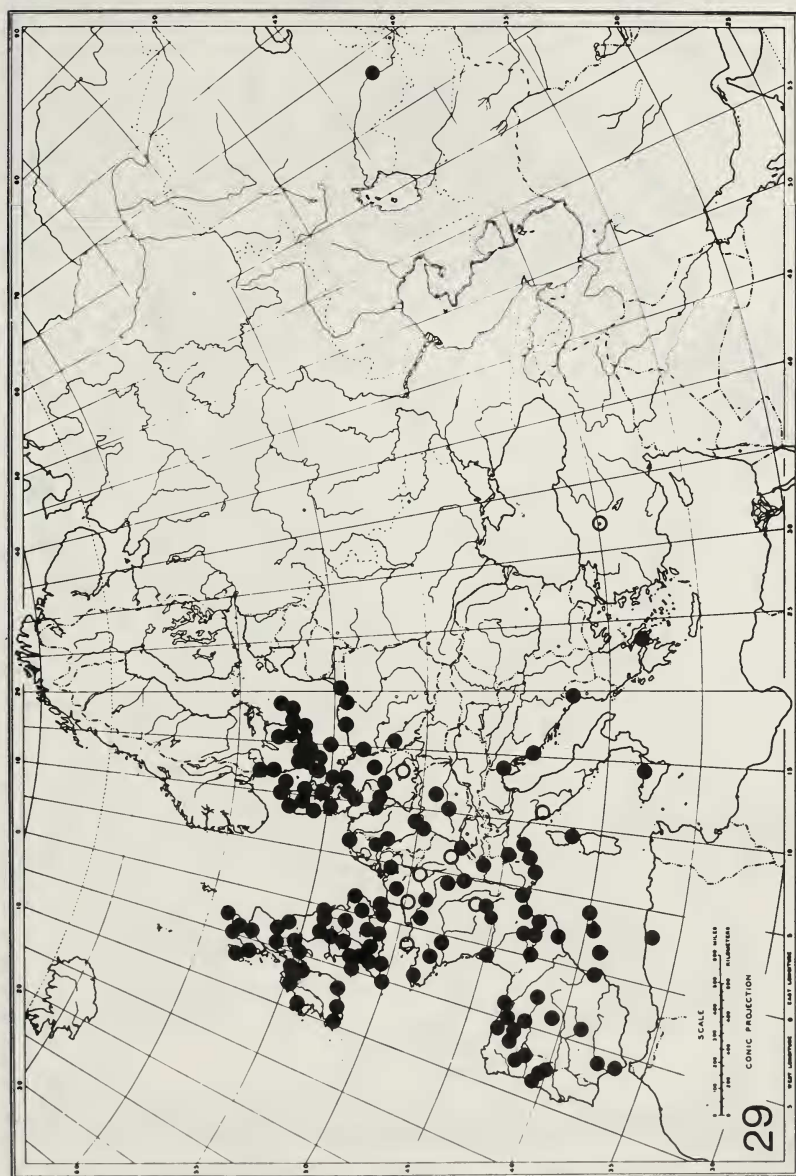

*Natural history.*— Nothing substantial is published, nor can much be inferred from label information about the natural history of this taxon. Teneral specimens are known from the month of August (Table 4). Two flight records are available for the month of July (Table 5). Because of the phylogenetic affinities of this taxon to *D. fasciventris*, it probably represents the ecological replacement of *D. fasciventris* in western North America.

*Distribution* (Fig. 33).— The range of this species extends from British Columbia, Canada, south to California, USA. All records are from localities west of the Rocky Mountains.

*Chorological relationships.*— *Dytiscus hatchi* is broadly sympatric only with *D. marginicollis*. It is narrowly sympatric with its closest relative, *D. fasciventris*, in southern British Columbia, Canada.

*Phylogenetic relationships.*— See notes under equivalent section in treatment of *D. fasciventris* and (Fig. 52).

*Material examined.*— A total of 222 specimens was examined of which 107 are males, 112 females, and sex was not determined for 3 specimens.

*Dytiscus cordieri* Aubé, 1838  
Figs. 3A, 9C, 16C, 21K, 23B, 34, and 52

*Dytiscus cordieri* Aubé 1838:108 (Type locality - "Boston...", Mass., USA. Type not seen). - Zimmermann 1920:246. -Wallis, 1950:51. -Hatch 1953:238. -Gordon and Post 1965:25. -Wallis and Larson 1973:110. -Larson 1975:400.

*Dytiscus sublimbatus* LeConte 1857:34 (Type locality - "Prairie Paso", Oregon Territory. Holotype female in LeConte collection, MCZC, labelled as follows: "Or.; *D. sublimbatus* Lec; Horn Coll H. 1485"). -Zimmerman 1920:246. -Hatch 1929:226. -Wallis and Larson 1973:110.

*Dytiscus marginalis; auctorum, nec* Linnaeus 1758. **Misidentification.** Sharp 1882:641 (*ex parte*). -Ganglbauer 1892:515 (*ex parte*). -Wickham 1895:151 (*ex parte*). -Roberts 1905:106 (*ex parte*). -Csiki 1908:508 (*ex parte*). -Reitter 1908:233 (*ex parte*). -Reitter 1909:46 (*ex parte*). -Gozis 1910:12 (*ex parte*). -Blunck 1913:47 (*ex parte*). -Schaufuss 1916:138 (*ex parte*). -Zimmermann 1920:250 (*ex parte*). -Guignot 1932:718 (*ex parte*). -Houlbert 1934:133 (*ex parte*). -Zimmermann and Gschwendtner 1938:47 (*ex parte*). -Guignot, 1947a:243 (*ex parte*). -F. Balfour-Browne 1950:270 (*ex parte*). -Zaitsev 1953:327 (*ex parte*). -Galewski 1971a:100 (*ex parte*). -Franciscolo 1979:665 (*ex parte*).

**Derivation of specific epithet.**— The meaning of this name is not mentioned specifically by Aubé (1838) but possibly it was derived to honour the French geologist, Pierre L.A. Cordier.

**Notes about type material.** - I have not seen the type(s) of *D. cordieri*. Severin (1892) records a syntype in the Royal Museum in Brussels, Belgium. Aubé's type locality, Boston, Massachusetts, USA, is based on a single male specimen provided by Chevrolat.

Sharp (1882:773) states that he had seen the holotype, but that it was a very mutilated specimen of *D. fasciventris*. Sharp wrote, "Aubé's description does not agree well with this individual, or with any other species, and I think it must have been made from this individual and supplemented or corrected from another species...". This is in contrast to the statement by Aubé (1838:108) that "...Je n'ai vu de ce Dytique qu'un seul individu...". Sharp (1882:638) used the LeConte name, *D. sublimbatus*, presumably because of this confusion over the type. After the holotype and more specimens from Aubé's original series are studied, his concept will be better understood, and nomenclatural changes may be necessary.

LeConte's *D. sublimbatus* was described from a specimen from Prairie Paso, "Oregon Territory". However, I have been unable to find this locality. The type of this name is a nonsulcate female.

**Diagnostic combination.**— Distinct in North America as the only species of which adults possess obtuse apices of metacoxal lobes and a yellow venter (Figs. 21K and 9C). The only other Nearctic species with venter of adults yellow are *D. circumcinctus* and *D. alaskanus* (some specimens); members of both species have acuminate metacoxal lobes.

**Description.**— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 3A; coloration of pterothoracic and abdominal sterna in Fig. 9C; median lobe of male in Fig. 16C; metacoxal processes in Fig. 21K; and frontal view of head in Fig. 23B.

**Taxonomic notes.**— I believe most records of *D. marginalis* in North America are based on specimens of *D. cordieri*, or on mislabelled specimens. Adult *D. cordieri* are most easily distinguished from *D. marginalis* by an elongate chevron (Fig. 23B) on the frons extended to the antennal bases. In addition, adult male specimens of these two taxa are easily separated by pronotal structure

(not explanate in *D. cordieri*, explanate in *D. marginalis*), and shape of apex of median lobe (rounded in *D. cordieri*, Fig. 16C, with distinct apical knob in *D. marginalis*, Fig. 17C). Adult females are more similar because those of *D. cordieri* are shallowly or indistinctly explanate laterally, while those of *D. marginalis* are more distinctly explanate. Female adults are best separated by association with males and distribution. Further discussion of the confusion between *D. cordieri* and *D. marginalis* is provided within the treatment of the latter.

*Variation.*— There is a geographic basis to the occurrence of sulcate females. Most eastern specimens are sulcate and most western specimens are nonsulcate. For example 59 of 67 adult females from Ontario were sulcate, while of 142 specimens examined by Larson (1975) and me from Alberta, British Columbia, Manitoba and Saskatchewan, 11 are sulcate.

Almost all adult specimens of *D. cordieri* have the distinctively elongate chevron of the frons. In a few specimens, however, this is difficult to see because of *post-mortem* discoloration. Once these specimens are sufficiently cleaned, it is quite distinctive.

Pterothoracic sternal coloration is predominantly yellowish. The darkest specimen seen, which is quite outside the normal range of variation, is illustrated in Fig. 9C. Infuscation is restricted to the central area of the metasternum and sutures of the sterna in most specimens.

*Natural history.*— Larval development is completed probably between mid-July and mid-August, because teneral adults have been collected in late July and throughout August (Table 4). I have no information about overwintering sites of adults, except one specimen from Aweme, Manitoba, 26.iv.30 (1 CNIC) was "taken under logs out of water". This record could represent an overwintering site, but could indicate just as easily an example of a poor choice for a landing during dispersal. Label data indicative of dispersal are presented in Table 5. Records predominate for April in the spring and post-emergence flight takes place from July to October.

Larson (1975:401) noted that adults of *D. cordieri* occur in a wide variety of types of water body, and furthermore, that most records of *D. cordieri* are represented by individuals, with the longest series he had seen from Alberta being three specimens. Larson suggested that this was because either of low population densities or of insufficient knowledge of microhabitat of adults.

Using data from museum specimens, I tallied the number of adult specimens collected on a single day by a single collector, hereafter referred to as a sample. Of 335 samples from almost the entire range of the species, the average was 1.6 specimens. A similar tally for adult *D. alaskanus* yielded 202 samples averaging 3.4 specimens. The latter perhaps is more typical of *Dytiscus* adults. Less than 20 of these samples of adult *D. cordieri* were of more than five specimens, including bottle-trapped samples, and most of these are from April or from late August to early October, and were probably collected during or shortly after dispersal flight. By inference, I conclude that adults of *D. cordieri* occur at a lower population density than do those of other species.

*Distribution* (Fig. 34).— This species is transcontinental in North America, ranging from Alaska and the Northwest Territories, south to central California and northern Colorado, with the most southern record being from Gastonia, North Carolina.

*Chorological relationships.*— In some part of its range, *D. cordieri* is sympatric with every other Nearctic species of *Dytiscus* except the Mexican *D. habilis*.

*Phylogenetic relationships.*— In my phylogenetic interpretation of *Dytiscus* (Fig. 52), I have placed this species in the *D. dimidiatus*-group on the basis of presence of rounded metacoxal processes, rounded apex of the median lobe, and absence of a distinct knob at the apex of the median lobe. Specimens of *D. cordieri* are phenetically quite distinct from other members of the *D. dimidiatus*-group and represent the only Nearctic members of the group.

*Material examined.*— A total of 691 adult specimens was examined of which 362 were males, 328 were females, and for one specimen sex was not determined.

*Dytiscus mutinensis* Pederzani, 1971  
Figs. 3B, 9D, 16D, 21L, 23G, 35, and 52

*Dytiscus dimidiatus* ab. *mutinensis* Fiori 1881:276 (Information about types below). - Zimmermann 1920:248. - Müller 1926:298. - Guignot 1932:715 (*ex parte*). - Zimmermann and Gschwendtner 1938:40. - F. Balfour-Browne 1950:285. - Zaitsev 1953:325. - Schaefflein 1971:87. - Franciscolo 1979:663.

*Dytiscus pisanus* var. *mutinensis*; - Guignot 1931a:7 (**Misidentification of *D. dimidiatus***), *quod vide*. - Richoux and Dufay 1986: 421.

*Dytiscus mutinensis* Pederzani 1971:220 (Information about types below). Schaefflein 1973:74.

*Derivation of specific epithet.*— From "Mutina", the Latin name of Modena, Italy, which is Fiori's type locality.

*Notes about type material.* — Fiori's type is discussed by Pederzani (1971). Pederzani, when elevating this taxon to specific rank, retained the same epithet, presumably to provide continuity in use of this name. For his new, species-level taxon, Pederzani designated a new type specimen from Italy for which he gives the following information: "Holotypus [male symbol]; Ravenna, pineta di S. Vitale, 20.ix.1970, leg. Pederzani." It is deposited in the Museo Civico di Storia Naturale de Milano, Italy (Pederzani, 1971:222).

*Diagnostic combination.*— Adults of this species are best separated by characters presented in the key. Supplemental character states distinguishing it from *D. dimidiatus* and *D. pisanus* are provided by Pederzani (1971).

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 3B; coloration of pterothoracic and abdominal sterna in Fig. 9D; median lobe of male in fig. 16D; metacoxal processes in Fig. 21L; and structure of protarsi in Fig. 23G.

*Taxonomic notes.*— This taxon has been confused with members of *D. dimidiatus* because adults are quite similar in external features. Pederzani (1971) was the first to distinguish this taxon as being of specific rank. As such, a new holotype was needed, and a specimen was so designated by that author.

Part of the taxonomic confusion arose because non-sulcate females of *D. dimidiatus* were assigned to *D. dimidiatus* ab. *mutinensis*. Guignot's (1931a, 1932) record of this aberration from France, Department of Bouches-du-Rhône, St. Rémy (1 MNHN) is such a non-sulcate female. Both *D. dimidiatus* and *D. mutinensis* have sulcate and non-sulcate states of elytra of females.

Franciscolo (1979:663-664) expresses reservations about the species-level separation of *D. mutinensis* and *D. dimidiatus*. As he infers, the longer metatarsomere V of male *D. dimidiatus* would be expected to have more punctures (approximately 60) than that of the shorter one of *D. mutinensis* (approximately 30), and this is one of the major differences used by Pederzani (1971) and me. Franciscolo notes that other differences between these putative species are very subtle.

In the south of France, females of *D. dimidiatus* have both sulcate and non-sulcate females. Furthermore, specimens from southern France and particularly those from the Camargue region are somewhat shorter, narrower and less robust. I interpret this variation as only a populational difference but such specimens are more similar to those of *D. mutinensis*. Some females from this region are non-sulcate; however, Leblanc (1982) has described sulcate females of this population as *D. mutinensis* var. *striatus*. Through the courtesy of P. Leblanc (Troyes, France) and F. Bameul (Bordeaux, France) I have studied three paratypes of this variety and I assign them to *D. dimidiatus*. I have not seen a specimen of my concept of *D. mutinensis* from France.

Richoux and Dufay (1986) conducted a detailed study of variation among specimens of *D. mutinensis* and *D. dimidiatus* from the south of France, Greece and Italy. They concluded that *D. mutinensis* is a variety of *D. dimidiatus* because population samples from the south of France and Greece exhibit intermediate character states.

I have maintained the separation of these taxa as species for the following reasons: 1, consistent, if slight, differences in shape of median lobe of males; 2, information provided by Franciscolo (1979) that specimens assignable to both taxa were taken in the same ponds; and 3, lack of intermediate specimens among the limited sample I have seen. Obviously, it will require further study of specimens from an array of localities as well as carefully constructed hypotheses to establish confidently the status of these names.

*Variation*.— I saw slight variation in external features of adults in 12 specimens of *D. mutinensis*. Of the five males examined in detail, number of punctures on the anterior surface of protarsomere V ranged between 24 and 34.

Presence or absence of the anterior yellow band of the pronotum varies, but when present, this band is quite narrow, in most less than 10% of width of lateral bands. Two of the four females from Corfu have slightly impressed grooves.

*Natural history*.— Pederzani (1971) notes a preference of adult specimens of *D. mutinensis* for lentic habitats with much vegetation and detritus. Adults occur in both open and shaded habitats, but locally. Angelini (1978) provides more detailed notes about habitats where specimens of *D. mutinensis* were collected, and adds occurrence in slowly moving water.

*Distribution* (Fig. 35).— This species occurs throughout Italy and around the Adriatic Sea. Guignot's record from France is discussed above. I suspect that the records from southern France provided by Théron (1975:106) will also prove to be non-sulcate females of *D. dimidiatus*. Therefore, the records from France do not appear on Fig. 35.

*Chorological relationships*.— Even though it occupies a small range, *D. mutinensis* is sympatric with all other European species except *Dytiscus lapponicus*.

*Phylogenetic relationships*.— I have interpreted *D. mutinensis* as the sister species of *D. dimidiatus* (Fig. 52), both of which are allied to *D. cordieri* and *D. pisanus*.

*Material examined*.— A total of 13 adult specimens was examined, of which 8 were males, and 5 were females.

*Dytiscus dimidiatus* Bergsträsser, 1778  
Figs. 3C, 10A, 17A, 21M, 23H, 36, and 52

*Dytiscus dimidiatus* Bergsträsser 1778:33 (Type locality -Hanau area of Hessen, West Germany. Type not seen). -Zimmermann 1920:247. -Guignot 1932:712. -Houlbert 1934:132.

Zimmermann and Gschwendtner 1938:40. -Guignot 1947a:242. -F. Balfour-Browne 1950:285. -F. Balfour-Browne 1953:27. -Zaitsev 1953:325. -Galewski 1971a:100. -Schaefflein 1971:87. -Pederzani 1971:222. -Franciscolo 1979:663. -Régil and Salgado 1984:134,135.

*Dytiscus dimidiatus* ab. *mutinensis*; Guignot 1932:715. -Guignot 1947a:242.

*Dytiscus pisanus* ab. *mutinensis*; Guignot 1931a:7.

*Dytiscus mutinensis*; Théron 1975: 106.

*Dytiscus mutinensis* var. *striatus* Leblanc 1982:239. (Type locality -"Étang du Charnier, près de Gallician, commune de Vauvert (Gard)", France. Type repository -MNHN). **NEW SYNONYMY.**

*Derivation of specific epithet.*— Latin for 'halved', presumably in reference to length of elytral sulci of adult females (Fig. 3C). - Adults of this species are best separated by characters presented in the key.

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 3C; coloration of pterothoracic and abdominal sterna in Fig. 10A; median lobe of male in fig. 17A; metacoxal processes in Fig. 21M; and protarsi in Fig. 23H.

*Taxonomic notes.*— For a discussion of the confusion of species among *D. mutinensis* and *D. dimidiatus* by previous taxonomists, see the equivalent section in the treatment of the former species.

*Variation.*— Slight variation in external features of adults was noted and consisted mostly of presence, absence and width of anterior and posterior yellow bands of the pronotum. The anterior yellow band was consistently less than 30% of the width of the lateral bands of the pronotum.

Most females have sulcate elytra. For a discussion of records of non-sulcate females, see taxonomic notes under *D. mutinensis*.

*Natural history.*— F. Balfour-Browne (1950) stated that adults of this species are typically found in fens with occasional records from more temporary or disturbed habitats. He also gives a flight record for May and a record of a teneral specimen for September.

Brancucci (1979) reported a maximum density of adults in marshes during the month of June near Cudrefin, Switzerland. Borchert (1938:17) characterizes this species in Europe as a resident of lowland habitats where occasional specimens are found over a wide variety of habitats. Pederzani (1971) implies that specimens live in both open, disturbed habitats as well as more mature ponds. Neither this species nor *D. mutinensis* are found as adults in lotic habitats in anything but very slowly running water. Korschelt (1923, 1924) gives further details about natural history of this species.

*Distribution* (Fig. 36).— This species occurs throughout Europe. In Scandinavia, I have no records north of about 62°N. The easternmost record is at about 41°E. I have seen specimens labelled simply "Africa" (CASC) but have not been able to find any precise locality records for Africa. Leblanc (1982) mentions that it is found in Saudi Arabia but I have not seen specimens from there.

*Chorological relationships.*— *Dytiscus dimidiatus* is sympatric with every other species of *Dytiscus* occurring in Europe.

*Phylogenetic relationships.*— See equivalent section under treatment of *D. mutinensis* (Fig. 52).

*Material examined.*— A total of 305 adults was examined, of which 156 are males and 149 are females.

*Dytiscus pisanus* LaPorte Compte de Castelnau, 1835

Figs. 3D, 10B, 17B, 21N, 23I, 37, and 52

*Dytiscus pisanus* LaPorte Compte de Castelnau 1835:98 (Type locality - "Pise", Italy. Lectotype, here selected - male in BMNH labelled: LECTOTYPE; SYNTYPE; Sharp coll., 1905-313; *Dytiscus pisanus* Lap., Italia [male symbol]; LECTOTYPE, *Dytiscus pisanus* LaPorte de Castelnau 1835, selected R.E. Roughley.). -Zimmermann 1920:253. -Guignot 1932:719. -Houlbert 1934:134. -Zimmermann and Gschwendtner 1938:44. -Guignot 1947a:244. -Guignot 1961:859. -Pederzani 1971:224. -Franciscolo 1979:666. -Régil and Salgado 1984:134,135.

*Dytiscus ibericus* Rosenhauer 1856:47 (Type locality - Algeciras, Spain. Type not seen.). - Zimmermann 1920:253.

*Dytiscus pisanus* var. *ibericus*; -Guignot 1931a:7. -Guignot 1932:719. -Zimmermann and Gschwendtner 1938:44. -Guignot 1947a:244. -Guignot 1961:859. -Franciscolo 1979:667.

*Dytiscus pisanus* var. *nonsulcatus* Zimmermann 1919:233 (Type locality - not given. Holotype in Zimmermann collection, ZSBS, labelled as follows:♀; Tanger, Rolph; Type; Holotypus, *Dytiscus pisanus* ♀ var. *nonsulcatus* Zim., Staatssamml. München.). -Zimmermann 1920:253. -Pederzani 1971:219.

*Derivation of specific epithet.*—"pisanus" is the adjectival form of the name of the type locality, Pisa, Italy.

*Diagnostic combination.*— European distribution, pronotum broadly margined with yellow on all sides, combined with rounded lobe of metacoxal process and detailed features presented in the key allow accurate determination of adult specimens. Also, the form of the median lobe of male adults is quite distinctive (Fig. 17B).

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 3D; coloration of pterothoracic and abdominal sterna in Fig. 10B; median lobe of male in Fig. 17B; metacoxal processes in Fig. 21N; and mesotarsi of females in Fig. 23I.

*Taxonomic notes.*— Guignot (1932) states that certain (unnamed) authors proposed to make *D. pisanus* a variety of *D. marginalis*. He provides several minor distinctions among adults of these species, and a major difference in form of the median lobe. These distinctions, in conjunction with those presented in the key, demonstrate that two species are represented, especially when supplemented with the information that *D. pisanus* is widely sympatric with *D. marginalis*.

Zimmermann (1919) erected *D. pisanus* var. *nonsulcatus* for female forms with smooth elytra. Many authors have used the name *ibericus* for this form, but Pederzani (1971) examined five specimens from MNHN determined as *Dytiscus ibericus* and states that they were sulcate.

*Variation.*— I have seen too few specimens of this taxon to assess patterns of variation. More than half of the specimens seen have the pterothoracic sterna piceous ventrally as in Fig. 10B. Associated with this coloration in most specimens is a darkening of abdominal sterna. Conversely, those specimens with lighter pterothoracic sterna tend to be closer to uniformly yellow in ventral coloration.

Guignot (1932:720) states that the non-sulcate form is quite rare. To his list of localities for non-sulcate females, I add only Godelleta, Spain (1 MCZC). Thus, the non-sulcate form is restricted to the southern and western parts of the range (southern France, Spain, Morocco and Algeria).

*Natural history.*— Guignot (1932) states that adults of *D. pisanus* live in calm, clear water. However, Pederzani (1971) notes a preference for running water or for pools in stream beds.

The larva of *D. pisanus* was described and compared to those of *D. circumflexus* and *D. semisulcatus* by Bertrand (1928). This species may complete larval development early in the year as Bertrand (1928: 17) records (presumably) mature larvae from April in Montpellier (Dept. Hérault, France).

*Distribution* (Fig. 37).— This species has a Mediterranean distribution, but does not occur as far north as 50°. The easternmost record is for the island of Crete, and the southernmost records are from Algeria and Morocco.

*Chorological relationships.*— Apparently sympatric with every other European species of *Dytiscus*. If its preference for running water is correct though, it may well occupy a distinctly different microhabitat from that of most co-occurring taxa.

*Phylogenetic relationships.*— The rounded apex of the median lobe indicates a close relationship to *D. mutinensis* and *D. dimidiatus*.

*Material examined.*— A total of 129 specimens was examined of which 50 were males and 79 females.

Fig. 34. Known distribution of *Dytiscus cordieri* Aubé.

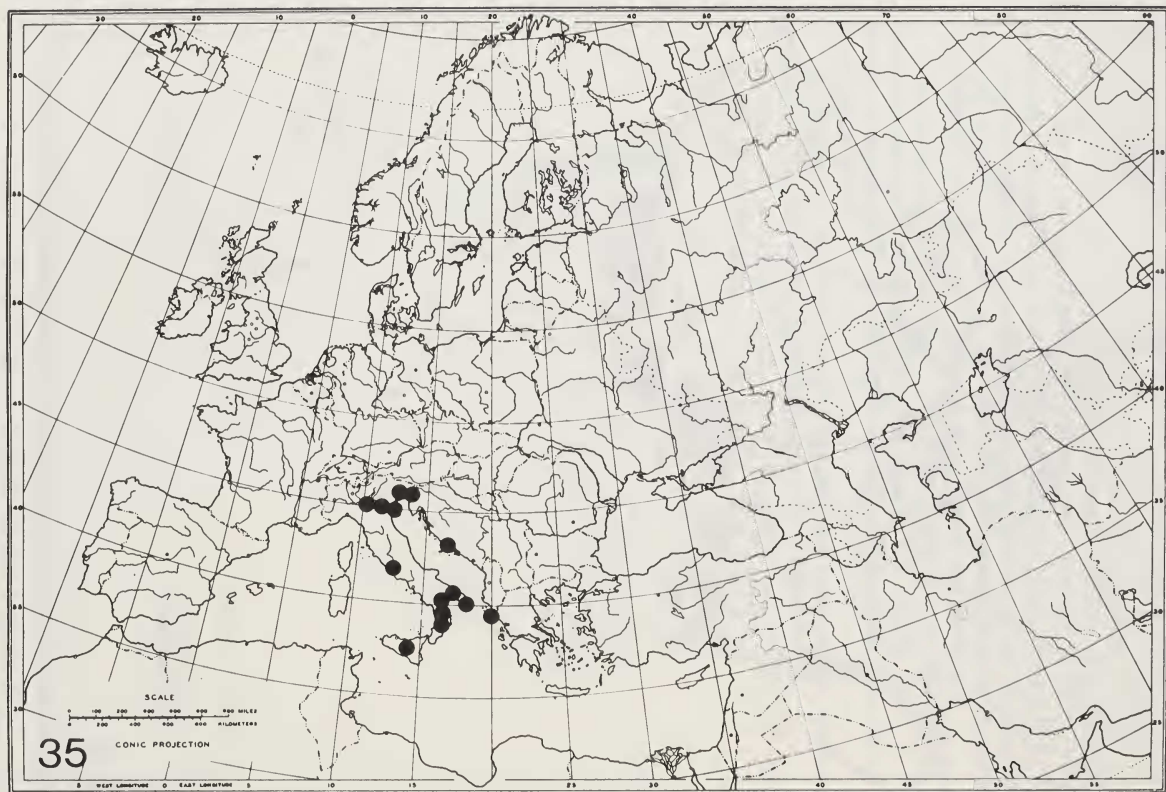

Fig. 35. Known distribution of *Dytiscus mutinensis* Pederzani.

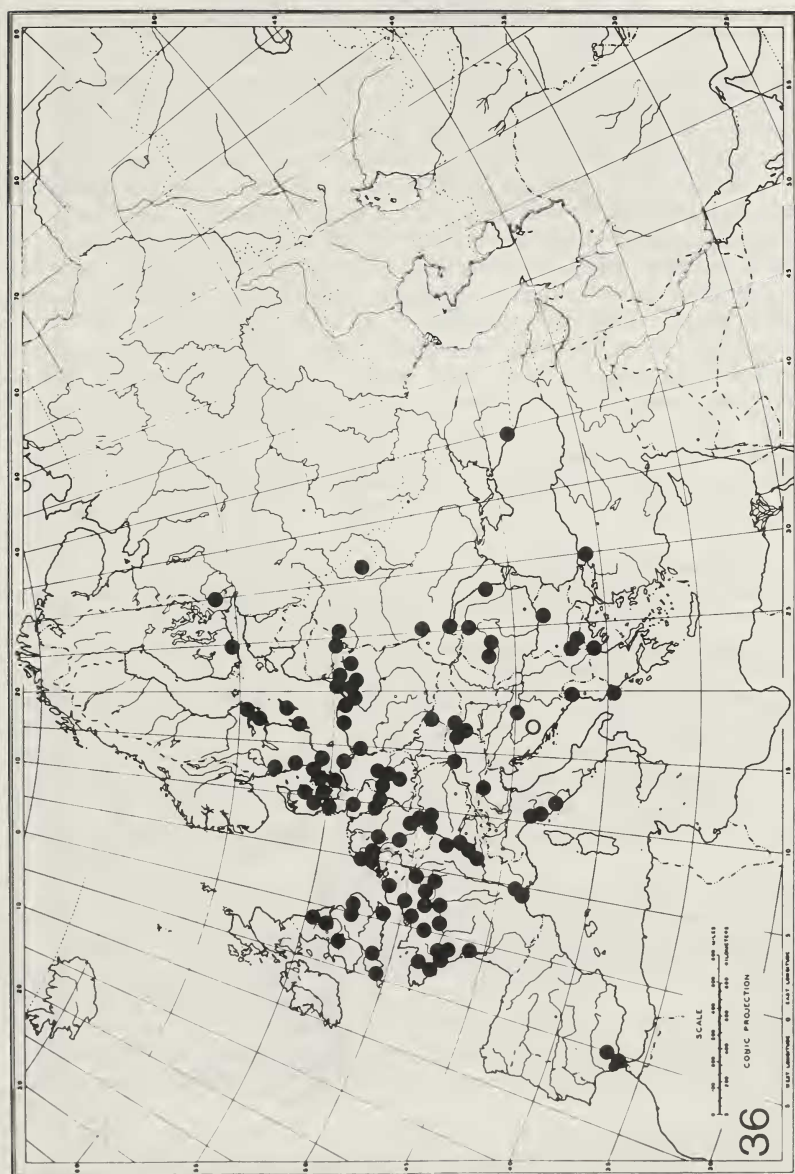

Fig. 36. Known distribution of *Dytiscus dimidiatus* Bergsträsser.

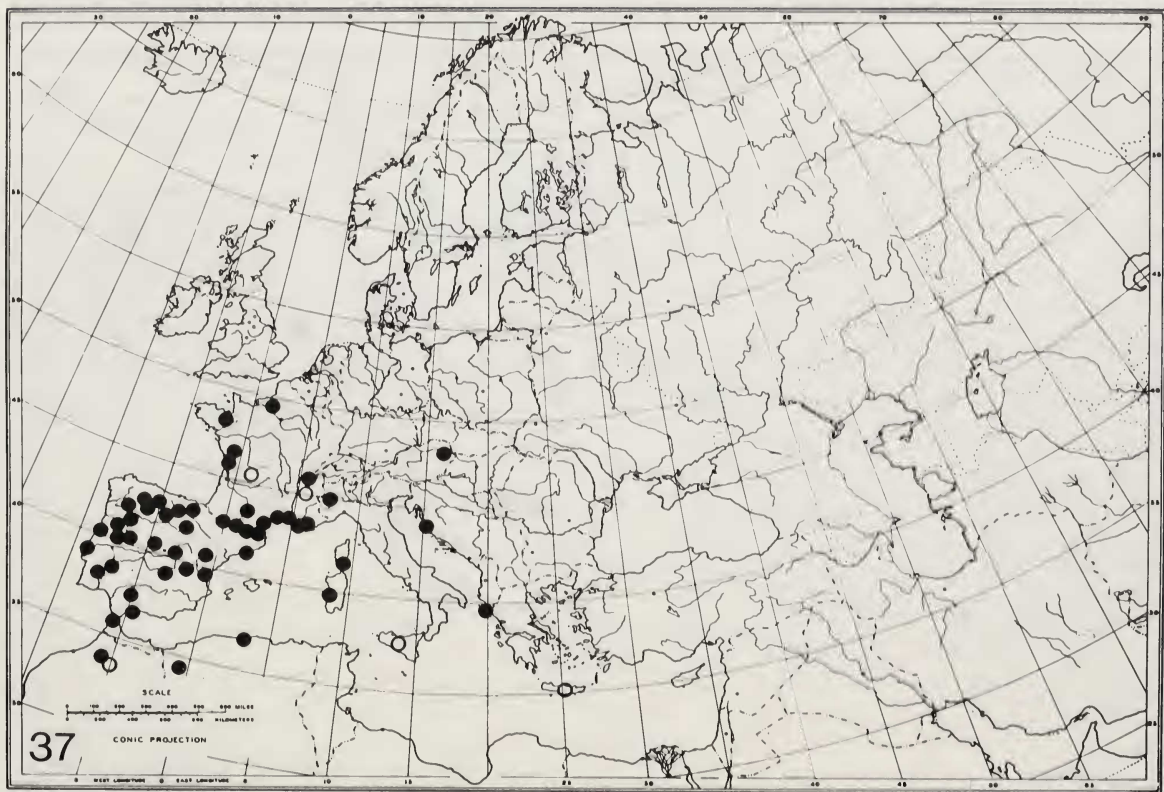

Fig. 37. Known distribution of *Dytiscus pisanus* Castelnau.

*Dytiscus marginalis* Linnaeus, 1758  
Figs. 3E, 10C, 17C–D, 22A–B, 38, and 52

*Dytiscus marginalis* Linnaeus 1758:411.

**Derivation of specific epithet.**— With reference to all sides of the pronotum, or alternatively, lateral edges of elytra being margined with yellow.

**Diagnostic combination.**— The combination of Palearctic distribution, acute but not acuminate metacoxal lobes, pronotum with yellow margin on all sides, and form of median lobe of males distinguish males of this taxon.

**Taxonomic notes.**— Some notes about confusion among *D. marginalis* and *D. cordieri* are presented under the treatment of the latter. Sharp (1882:641) was the first to ascribe *D. marginalis* to the Nearctic fauna based on a female specimen labelled "am. bor. int., montagnes rocheuses", and another individual "...said to be from North America, in Murray's collection." The latter record refers to a specimen of *D. cordieri*. The former specimen, provided by Castelnau, is deposited in BMNH and is a sulcate female of *D. marginalis*. I believe this specimen to be mislabelled. Similarly, I have seen the following specimens of *D. marginalis* which presumably have incorrect locality information: America (1 HNHM), "Ind." (1 CNIC), Canada? (1 MCZC), Detroit, Mich. (3 ICCM), Grand Portage, Labr. 2.vi.17 (1 ICCM), Montreal, Quebec (1 ICCM), Allegheny Co., Pa., vi.25 (1 ICCM), Quebec (1 ICCM), Ridgeway, Ont. (1 ICCM), and Toronto, Ont., vi.14 (1 ICCM).

As Brinck (1946:146) pointed out, there is little difference in form of the median lobe among eastern and western Palearctic specimens of *D. marginalis*. However, there are major differences in ventral coloration, and these colour forms are geographically vicariant. Thus, I have decided to treat *D. marginalis* as two subspecies: 1, the nominate, western Palearctic form, characterized by predominantly yellow pterothoracic sterna; and 2, an eastern Palearctic form for which the name *D. czerskii* is available and in which adults have the pterothoracic sterna appreciably marked with black or piceous. The two forms are allopatric and could represent taxa of specific level. However, differences in form of the median lobe are too slight to support such a conclusion, without additional supporting evidence. I have not seen intermediates in type of ventral coloration.

**Distribution.**— This ubiquitous Palearctic species, when the combined ranges of both subspecies are considered, includes most of the Palearctic region.

**Chorological relationships.**— The aggregate range of both subspecies of this species suggest that it is sympatric with every other Palearctic species of *Dytiscus* except possibly *D. sinensis*.

**Phylogenetic relationships.**— Presence of character states such as acute metacoxal lobes, margined pronotum, as well as those found in form of the median lobe of males, indicate that it is closest to *D. persicus* and *D. delictus* (Fig. 52).

*Dytiscus marginalis marginalis* Linnaeus, 1758, NEW STATUS

*Dytiscus marginalis* Linnaeus 1758:411 (Type area - "Europae". Type not seen.). -Zimmermann 1920:249. -Müller 1926:298. Guignot 1932:715. -Houlbert 1934:133. -Zimmermann and Gschwendtner 1938:47. -Guignot 1947a:243. - F. Balfour-Browne 1950:270. -F. Balfour-Browne 1953:27. -Zaitsev 1953:327. -Galewski 1971a:100. -Schaefflein 1971:88. -Franciscolo 1979:665. -Régil and Salgado 1984:134,135.

*D. marginalis*, auctorum. Nearctic records are *D. cordieri*, quod vide, **Misidentification**.

- Dytiscus semistriatus* Linnaeus 1758:412 (Type area - "Europae". Type not seen.). - Zimmermann 1920:250.
- Dytiscus totemarginalis* DeGeer 1774:391 (Type locality not stated. Type Material - see Notes, below). - Zimmermann 1920:250.
- Dytiscus conformis* Kunze 1818:58 (Type locality - "Leipzig". Type not seen.). - Zimmermann 1920:250.
- Dytiscus marginalis* var. *conformis* Kunze; - Zimmermann 1920:250. Müller 1926:298. - Guignot 1932:715. - Zimmermann and Gschwendtner 1938:47. - Guignot 1947a:243. - F. Balfour-Browne 1950:250. - Zaitsev 1953:327. - Schaefflein 1971:88. - Franciscolo 1979:665.
- Dytiscus submarginalis* Stephens 1828:90 (Type locality - "taken near London, England". Lectotype male, selected here, in BMNH, labelled as follows: "LECTOTYPE; SYNTYPE; LECTOTYPE, *Dytiscus submarginalis* Stephens, selected R.E. Roughley").
- Dytiscus circumductus* Serville 1830:90 (Type locality - near Paris, France. Type not seen.). Zimmermann 1920:251.
- Dytiscus marginalis* form *semicostata* Reineck 1921:117 (Type locality - "...in Kurland in der Misse-Niederung." Type not seen.). - Guignot 1932:715. - Zimmermann and Gschwendtner 1938:47. - Guignot 1947a:243. - F. Balfour-Browne 1950:240. - Zaitsev 1953:327.

*Notes about type material.*— A lectotype of *D. submarginalis* is designated above. Type material for most other junior synonyms was not seen. However, three specimens of *D. totemarginalis* were examined from the DeGeer collection, Riksmuseet, Stockholm. The header label for these specimens reads: "2. *D. totemarginalis* p. 391, *D. marginalis* L. ♂ - *D. semistriatus* L. ♀". Two males and a female are in the series and each bears a square, orange label which is white on the lower surface. All specimens are missing parts of legs but otherwise are in good condition. No lectotype is designated.

*Diagnostic combination.*— The yellow pterothoracic sterna and western Palearctic distribution, in combination with the diagnostic combination of the species, are sufficient to identify adult members of *D. marginalis marginalis*.

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 3E; coloration of pterothoracic and abdominal sterna in Fig. 10C; median lobe of male in Fig. 17C; and metacoxal processes in Fig. 22A.

*Variation.*— As noted above, form of the median lobe of adult males varies only slightly among subspecies, and variation within subspecies is even less. Other aspects of variation include pronotal width, coloration of pterothoracic sterna, and sulcate or non-sulcate elytra of females.

Males and females from higher elevations in the Pyrenees and Cantabrian Mountains have the pronota narrower than the base of the elytra. In lowland specimens, pronota are distinctly broader than elytral bases. The latter is true for lowland specimens from central Spain, and I have therefore not treated this form as subspecifically distinct. It is more likely that the change in pronotal form is due to dietary and thermal effects of cold, oligotrophic alpine lakes and ponds.

Sharp (1882) discussed a specimen, which I have seen, of *D. marginalis marginalis* with expanded dark fasciae on the abdominal sterna. This specimen is a male and the median lobe is protruding, but the apex is damaged. After detailed comparison of this specimen with specimens of other Palearctic species, I judge the specimen to belong to *D. persicus*, even though labelled as coming from Europe. Others (e.g., Zaitsev 1953) have mentioned increased infuscation of the abdominal sterna. In all specimens that I have seen there is virtually no infuscation of the abdominal venter except for very narrow infuscation along

abdominal sutures ventrally (Fig. 10C). Thus, adults of this subspecies are best separated from members of *D. marginalis czerskii* on the basis of lack of appreciable pterothoracic infuscation and distribution. See also notes under variation of *D. marginalis czerskii*.

Females of *D. marginalis marginalis* with non-sulcate elytra appear sporadically throughout the entire range of this taxon. There may be geographic patterns to the frequency of occurrence of the two female forms. For instance, F. Balfour-Browne (1950) states that the non-sulcate form is quite rare in Britain, or at least has been since 1828. Guignot (1932) states that the non-sulcate form occurs throughout France but is more common in central and western France. The non-sulcate form occurs throughout Italy, but Franciscolo (1979) noted a trend for it to become slightly more common in the south. For central Europe, Schaefflein (1971) characterizes the grooved female as most common, but that at certain localities in the northern and northeastern regions, the smooth form is more numerous than the grooved form. Guignot (1933) mentions that the smooth form is more common in the southern USSR, while Zaitzev (1953) apparently extends this trend to all of the USSR.

*Natural history.*—The natural history of adult and larval stages of this subspecies has been intensively studied for many years in Europe. Many of the publications are cited by Zimmermann (1920:251), and are discussed and augmented in the treatment edited by Korschelt (1923, 1924).

*Distribution* (Fig. 38).—This subspecies is widespread in the western and central parts of the Palearctic region.

*Material examined.*—A total of 1382 adult specimens was examined, of which 619 were males, 762 were females, and sex of one specimen was not determined.

### *Dytiscus marginalis czerskii* Zaitsev 1953, NEW STATUS

*Dytiscus marginalis, auctorum*; Sharp 1874:417. -Sharp 1882:641 (*ex parte*). -Brinck 1946:146.

-J. Balfour-Browne 1946:453. -Guignot 1947a:244 (*ex parte*).

*Dytiscus czerskii* Zaitsev 1953:328. **NEW SYNONYMY.** (Type locality - not specified, but all localities listed are in Primorskij Kraj (Maritime Territory), USSR).

*Derivation of subspecific epithet.*—Named in honour of A.I. Cherskii, who collected the type specimen.

*Notes about type material.* - I have not seen Zaitzev's type of this taxon, which, according to his preface, is deposited in the Zoological Institute of the Academy of Sciences of the USSR in Leningrad. I have, however, seen specimens authenticated by Zaitzev.

*Diagnostic combination.*—The infusate pterothoracic sterna and eastern Palearctic distribution, in combination with the diagnostic combination of the species, are sufficient to identify adult members of *D. marginalis czerskii*.

*Description.*—Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is not shown; coloration of pterothoracic and abdominal sterna in Fig. 10D; median lobe of male in Fig. 17D; and metacoxal processes in Fig. 22B.

*Taxonomic notes.*—The slight character differences mentioned by Zaitsev (1953) among specimens of *D. marginalis* and *D. czerskii* are insufficient in themselves to warrant species-level status. This is true also of differences in form of the median lobe, and I have therefore used subspecific rank for these two forms.

*Variation*.— I have seen too few specimens of this taxon to assess patterns of variation. Zaitsev (1953) writes that the ventral colour of *D. czerskii* is similar to that of *D. marginalis*. All specimens of *D. marginalis czerskii* that I have seen have a much greater development of infuscation on the venter than is typical of more western populations of *D. marginalis*. All specimens have sternum VI broadly infusate, and most specimens have a broad infusate band on sternum II.

As noted under the section concerning variation in *D. marginalis marginalis*, Zaitsev implies that the non-sulcate form is the most common in the USSR. This is in marked contrast to the condition of female *D. marginalis czerskii*. Zaitsev (1953) states that all 16 females which he had seen were sulcate. I have seen an additional eight female specimens, all of which have sulcate elytra.

*Natural history*.— Nothing has been published about natural history of this subspecies.

*Distribution* (Fig. 38).— This subspecies is found in the Amur and Maritime regions of the USSR, and in Japan, and is to be expected in the northeastern regions of China. In addition, the records cited by Yoon and Ahn (1988) for North Korea may well refer to this subspecies.

*Material examined*.— A total of 20 adult specimens was examined, of which six are males and 14 are females.

*Dytiscus persicus* Wehncke, 1876  
Figs. 11A, 18A, 22C, 39, and 52

*Dytiscus persicus* Wehncke 1876:52 (Type area - "Persien". Holotype female in Wehncke collection, MNHN, labelled as follows: "Persia, settente., 1862-63, Coll. G. Doria; type; Persia; HOLOTYPE, *Dytiscus persicus* Wehncke, examined R.E. Roughley"). - Zimmermann 1920:-235. - Zimmermann and Gschwendtner 1938:46. - Zaitsev 1953:327.

*Dytiscus marginalis*; Sharp 1882:641 (*ex parte*). **Misidentification.**

*Derivation of specific epithet*.— Named for "Persia", the type area.

*Notes about type material*. — Wehncke's description indicates that he had seen only one non-sulcate female of this species from the Dohrn collection. The holotype was placed beside a large label reading "*persicus* mihi" in Wehncke's handwriting. The BMNH contains two other non-sulcate female specimens labelled: "Co-type; Persia, settente., 1862-63, coll. G. Doria; Sharp coll., 1905-313 [label inverted]; Ispahan. Persia. J. Doria 1862-63, *persicus*", the bottom label in David Sharp's handwriting. These BMNH specimens cannot be considered part of the type series of *D. persicus* because, based on Wehncke's original description, they were not seen by him, even though they are part of the same series of specimens. Sharp may have obtained the specimens from Doria. Sharp (1882) states that these specimens may be from Isfahan (=Esfahan), Iran, but does not mention the source of this information.

*Diagnostic combination*.— This is the only western Palearctic species other than *D. pisanus*, *D. circumcinctus* and *D. lapponicus* of which adults have transverse black fasciae on the abdominal venter. The latter two have longer metacoxal processes, while *D. persicus* and *D. pisanus* have quite separate ranges.

*Description*.— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is not shown; coloration of pterothoracic and abdominal

sterna in Fig. 11A; median lobe of male in Fig. 18A; and metacoxal processes in Fig. 22C.

*Taxonomic notes.*— See notes provided under *D. marginalis*.

*Variation.*— I have seen only 19 specimens assignable to this name, and have therefore little information about variation. Of the ten females examined, four have sulcate elytra.

*Natural history.*— Unknown.

*Distribution Map, Fig. 39.*— Zaitsev (1953:328) records this species from Iran, northeastern Turkey and from the southern coast of Crimea, Dagestan and Transcaucasia in the USSR. I have assigned a specimen from Narin, Afghanistan to this species.

*Chorological relationships.*— I have seen few specific locality records for any species from the range of *D. persicus*, and cannot make a confident statement of co-occurrence with other taxa. However, it may be sympatric with *D. semisulcatus*, *D. dimidiatus*, *D. marginalis*, *D. circumflexus* and *D. thianshanicus*.

*Phylogenetic relationships.*— Adult members of this species show characteristics indicating that *D. persicus* is related to *D. marginalis* and *D. delictus*.

*Material examined.*— A total of 19 adult specimens was examined, of which nine are male and 10 are females.

*Dytiscus delictus* (Zaitzev, 1906)

Figs. 4A, 11B, 18B, 22D, 23J, 40, and 52

*Macrodytes delictus* Zaitzev 1906:28 (Type locality - Chaborovsk, Chaborovsk Kraj, RSFSR, USSR. Type not seen).

*Dytiscus delictus*; -Zimmermann 1920:247. -Zimmermann and Gschwendtner 1938:43. -Zaitzev 1953:326.

*Derivation of specific epithet.*— Not stated by Zaitzev. The Latin word *delictus* means "faulted" or "failed", but the significance of this epithet is not apparent.

*Notes about type material.* - I have not seen type specimens of this species, but have seen specimens authenticated by Zaitzev.

*Diagnostic combination.*— Eastern Palearctic distribution, acute metacoxal lobes, and fasciate abdominal sterna distinguish adults of this taxon from those of other species of *Dytiscus*.

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 4A; coloration of pterothoracic and abdominal sterna in Fig. 11B; median lobe of male in Fig. 18B; metacoxal processes in Fig. 22D; and mesotarsi of females in Fig. 23J.

*Taxonomic notes.*— Zaitzev (1906) accepted *Macrodytes* as a distinct genus, and assigned his species, *delictus*, to it.

*Variation.*— I have seen too few specimens to assess patterns of variation.

*Natural history.*— Unknown.

*Distribution Map, Fig. 40.*— I have seen specimens from Chabarovsk Kraj, Primorskij Kraj, and Sachalin Oblast of the eastern USSR. Zaitzev (1953) reports specimens from the same general area. This species may also occur in northeastern China and Japan.

*Chorological relationships.*—*Dytiscus delictus* is sympatric with *D. sharpi*, *D. marginalis czerskii*, *D. dauricus*, *D. circumcinctus*, and *D. thianshanicus*.

*Phylogenetic relationships.*— This species is the eastern vicar of *D. persicus* (Fig. 52).

*Material examined.*— A total of 20 adult specimens was examined, of which nine are males and 11 are females.

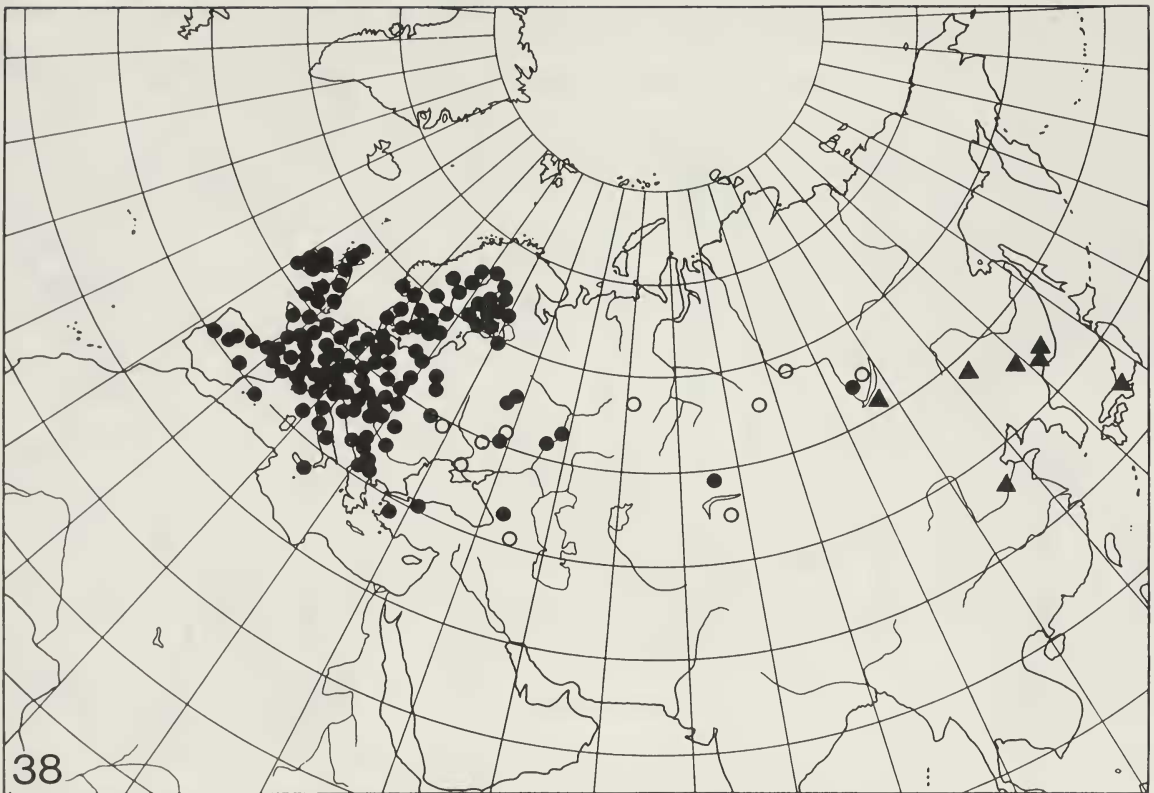

Fig. 38. Known distribution of *Dytiscus marginalis marginalis* Linnaeus (circles) and *D. marginalis czerskii* Zaitsev (triangles).

Fig. 39. Known distribution of *Dytiscus persicus* Wehncke

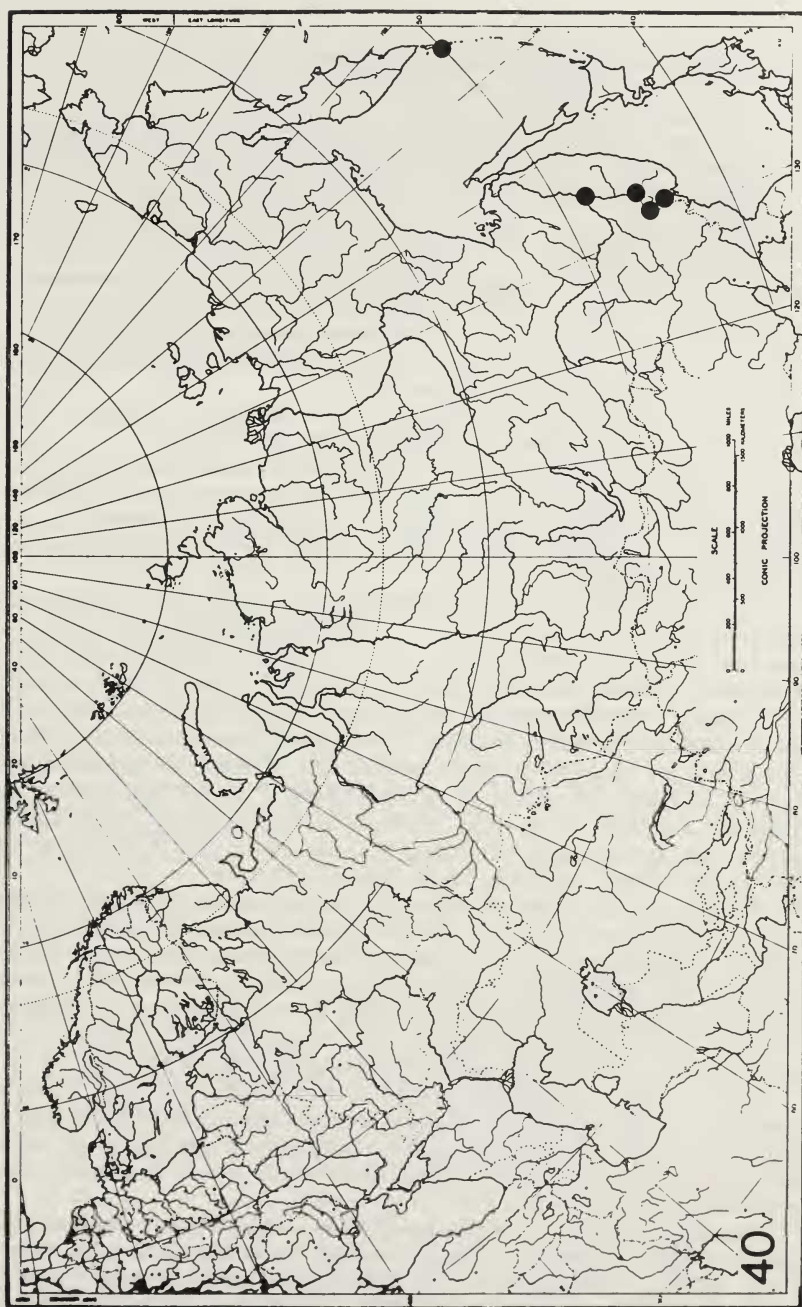

Fig. 40. Known distribution of *Dytiscus delictus* (Zaitzev).

*Dytiscus latissimus* Linnaeus, 1758  
Figs. 4B, 11C, 18C, 22E, 41, and 52

*Dytiscus latissimus* Linnaeus 1758:411 (Type area - "Europae". Type not seen.). -Zimmermann 1920:242. -Guignot 1932:730. -Houlbert 1934:132. -Zimmermann and Gschwendtner 1938:35. -Guignot 1947a:247. -Zaitsev 1953:321. -Schaefflein 1971:86. -Franciscolo 1979:671.

*Dytiscus amplissimus* Müller 1776:69 (Type area - not stated, presumably Denmark). - Zimmermann 1920:243.

*Dytiscus anastomozans* Well 1781:386 (Type locality - not known to me. Type not seen.). - Zimmermann 1920:244.

*Derivation of specific epithet.*— This name is derived from the superlative form of Latin *latus*, meaning "broad" or "wide". It is an apt name for this taxon because of the great width of the body of adults.

*Diagnostic combination.*— The great width of the body and widening of the elytral epipleura are sufficient to distinguish adults of this taxon.

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 4B; coloration of pterothoracic and abdominal sterna in Fig. 11C; median lobe of male in Fig. 18C; and metacoxal processes in Fig. 22E.

*Taxonomic notes.*— Most recent European workers have arranged the species of *Dytiscus* in two subgenera: the nominate subgenus, and subgenus *Macrodytes* Thomson. Members of *D. latissimus* have traditionally been placed in subgenus *Dytiscus*. The type species of *Dytiscus*, however, is *D. marginalis*, and the group of species generally treated as belonging to *Macrodytes* should in fact be assigned to subgenus *Dytiscus*. Despite such nomenclatural problems, it is clear that the intention of earlier authors was to isolate *D. latissimus* in a separate subgenus because of its distinctiveness. I do not believe that any subgeneric distinction is necessary within *Dytiscus*, and based on phylogenetic analysis it is not warranted for members of *D. latissimus*. For further discussion of this nomenclatural confusion, see the generic treatment.

*Variation.*— Non-sulcate females of *D. latissimus* are not known. This is unique among Palearctic taxa of *Dytiscus* except possibly for *D. marginalis czerskii*. However, only a few specimens of the latter taxon are known. Such a uniform condition of sulcate females suggests that females are under strong selective pressure for grooved elytra. Study of the behavioural function, and hydrodynamic importance of sulci in this species may provide the key to understanding evolution of grooved elytra among members of *Dytiscus*.

*Natural history.*— Guignot (1932), Zaitsev (1953), and other European authors characterize the habitat of this species as large bodies of water; that is, large ponds and lakes, although I am not sure whether or not this species occurs in open water within this habitat. Many specimens have been recorded as being collected in fish weirs.

*Distribution (Fig. 41).*— Occurs in the northern portions of the Palearctic region, except Great Britain. The easternmost record that I have seen is from USSR, RSFSR, Altajskij Kraj, Utkul' (52° 43'N 84° 36'E) but this species is undoubtedly more widespread in USSR. The southernmost record is from Yugoslavia, probably associated with long range dispersal (Apfelbeck 1904:308).

*Chorological relationships.*— I have few records from the far eastern Palearctic Region, and it is therefore difficult to assess areas of sympatry with such species as *D. sharpi*, *D. delictus*, *D. marginalis czerskii*, *D. thianshanicus*,

*D. latro* and *D. sinensis*. The known range of *D. latissimus* indicates sympatry with *D. semisulcatus*, *D. dimidiatus*, *D. pisanus*, *D. marginalis marginalis*, *D. circumcinctus*, *D. dauricus*, *D. lapponicus* and *D. circumflexus*. It is not sympatric with *D. mutinensis* and *D. persicus*.

*Phylogenetic relationships*.—Members of *D. latissimus* have the metacoxal processes acuminate, but less so than more advanced members of the genus such as *D. lapponicus*, *D. circumflexus*, etc. However, the median lobe is without an apical knob, which I interpret as a secondary loss, which has also occurred in *D. alaskanus*. I have placed *D. latissimus* as the most plesiotypic of those taxa which have acuminate metacoxal lobes (Fig. 52).

*Material examined*.—A total of 428 specimens was examined, of which 208 are males and 220 are females.

*Dytiscus circumcinctus* Ahrens, 1811

Figs. 4C, 11D, 18D, 19A, 22F, 42, 43, and 52

*Dytiscus circumcinctus* Ahrens 1811:67 (Type locality - not known to me. Type not seen.). - Zimmermann 1920:244. - Hatch 1929:227. - Guignot 1932:720. - Houlbert 1934:134. - Zimmermann and Gschwendtner 1938:54. - Guignot 1947a:244. - F. Balfour-Browne 1950:275. - LaRivers 1951:404. - F. Balfour-Browne 1953:27. - Hatch 1953:238. - Zaitsev 1953:331. - Gordon and Post 1965:25. - Galewski 1971a:88. - Schaefflein 1971:88. - Larson 1975:401. - Franciscolo 1979:669.

*Dytiscus flavocinctus* Hummel 1823:17 (Type area - "Livonie". Type not seen.). - Zimmermann 1920:245.

*Dytiscus circumcinctus* var. *flavocinctus* Hummel; - Zimmermann 1920:245. - Guignot 1932:720. - Zimmermann and Gschwendtner 1938:54. - Guignot 1947a:244. - F. Balfour-Browne 1950:277. - Zaitsev 1953:331. - Schaefflein 1971:88. - Franciscolo 1979:669.

*Dytiscus angustatus* Stephens 1828:88 (Type locality - "Bomere, Salop.", England. Lectotype male selected here from Stephens collection, BMNH, and labelled as follows: LECTOTYPE; SYNTYPE; LECTOTYPE, *Dytiscus angustatus* Stephens selected R.E. Roughley). - Zimmermann 1920:245.

*Dytiscus dubius* Gyllenhal 1827:372 (Type locality - not stated. Type not seen.). - Zimmermann 1920:245.

*Dytiscus ooligbuckii* Kirby 1837:74 (Type locality - "Great Bear Lake River", N.W.T., Canada. Type - see Larson 1975:401.). - Zimmermann 1920:247.

*Dytiscus circumscriptus* Boisduval and Lacordaire 1835:300 (Type locality - near Paris, France. Type not seen.). Zimmermann 1920:245. - Houlbert 1934:134.

*Dytiscus anxius* Mannerheim 1843:218 (Type locality - "Sitkha", Alaska. Type not seen.). - Zimmermann 1920:244. - F. Balfour-Browne 1950:277. - Leech and Chandler 1956:323. - Wallis and Larson 1973:110. - Larson 1975:401.

*Dytiscus fusco-striatus* Motschulsky 1859:167 (Type locality - Fort Ross near San Francisco, California, U.S.A. Type not seen.). - Zimmermann 1920:248.

*Dytiscus confusus* Motschulsky 1860:101 (Type area - "...dans toute la Sibérie orientale, jusqu'au Kamtschatka, et a été rapporté du fl. Amour...". Syntype male in MNHM labelled: SYNTYPE; *Dytiscus confusus* Mots., Dauria, [illegible], 52" [or 62"] [yellow circular label]; 1; *Dytiscus* ♂ *confusus* Daur. Motsch.; Museum Paris, coll de Marseul 1890; SYNTYPE, *Dytiscus confusus* Motschulsky 1860, examined R.E. Roughley). - Zimmermann 1920:245.

*Dytiscus circumcinctus* ab. ♂ *striatus* Bruce 1931: 190 (Type locality - "Kalmar, Ljungbyholm", Sweden. Type repository - not stated. Type not seen.).

*Dytiscus albionicus; auctorum, nec* Motschulsky 1859:166. **Misidentification of *D. marginicollis*, quod vide.**

*Dytiscus dauricus; auctorum, nec* Gebler 1832:39. **Misidentification.** - Zimmermann and Gschwendtner 1938:55 (*ex parte*).

*Derivation of specific epithet*.—This epithet is formed from the Latin words *circum* meaning around or on all sides, and *cinctum*, girdle or belt (Brown

1956). The name possibly refers to the yellow band around the dorsal edge of the eye of adults.

*Notes about type material.*— F. Balfour-Browne (1950) discussed many of the taxonomic problems associated with this species. Larson (1975) provides details about the type of *D. ooligbuckii*. I examined the type series of *D. angustatus* within the Stephens collection, BMNH. A lectotype is designated above, but because of the short pins used for Stephens' specimens, these are pinned beside the lectotype. In addition, there is a sulcate female specimen which is a syntype.

As noted above, I have seen a male syntype of *D. confusus* Motschulsky. My reasons for considering this specimen to be a part of the type series are: 1, the label on the box in de Marseul's collection as discussed under the treatment of *D. dauricus*; 2, the name *D. confusus* is on this list; 3, one of the labels ("*Dytiscus* ♂ *confusus* Daur., Motsch.") appears to be in Motschulsky's handwriting, by comparison with handwriting samples shown in Horn and Kahle (1935-37, Plate XVI, Fig. 23, and Plate XXI, Fig. 33); and 4, Motschulsky, in his discussion of this species, implies that he had seen a number of specimens from diverse localities. I have not designated this syntype as lectotype because it is incomplete, lacking its head, and having only the right foreleg complete.

*Diagnostic combination.*— Adults possess the following combination of character states: pronotum margined with yellow on all sides, acuminate metacoxal processes, predominantly yellow pterothoracic sterna, and eyes dorsally surrounded by narrow yellow band.

*Description.*— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 4C; coloration of pterothoracic and abdominal sterna in Fig. 11D; median lobe of male in Figs. 18D and 19A; and metacoxal processes in Fig. 22F.

*Taxonomic notes.*— Many names have been proposed for this species, presumably because it is very widespread and exhibits a certain amount of colour and structural variation. Samples from particular localities are generally uniform in colour and size and if compared with samples from adjacent localities, then assignment is usually not difficult. Taxonomic problems arise when comparing specimens from widely separated localities. In the latter example I have referred consistently to shape of the median lobe for evidence on which to make taxonomic judgments. Median lobes shown in Figs. 18D and 19A are typical of the variation in form of the median lobe; yet, the specimens are from localities (Edmonton, Alberta, Canada and Berlin, West Germany) from more than half of the Holarctic Region apart. The form of the median lobes of these specimens is very similar and therefore I have assigned them both to the same taxon. Another factor which has led to a proliferation of names is the occurrence of both sulcate and non-sulcate females in most populations of *D. circumcinctus*. Most early workers considered the two forms to be representative of separate taxa (see Blunk 1913 for discussion).

As noted above in the discussion of *D. marginicollis*, I have transferred the name *D. albionicus* from a junior synonym of *D. circumcinctus* to a junior synonym of *D. marginicollis*. One reason for this transfer was that *D. circumcinctus* is absent from California. Nevertheless I have retained the name *D. fuscostriatus* as a junior synonym of *D. circumcinctus* even though it was described from the same type locality (San Francisco). I have followed Larson (1975) in the present placement of *D. fuscostriatus* in part because Motschulsky

(1859) describes the venter of the type female as testaceous and the elytra as sulcate. Study of Motschulsky's types will be needed to clarify this problem.

*Variation.*— As noted above there is very little variation in form of the median lobe of male specimens from throughout the entire, Holarctic range of *D. circumcinctus*. One of the major features of variation in the median lobe of adult males is positive correlation among size of specimens and length of the median lobe. Increased or shortened length of the median lobe does not significantly affect shape of the apical portion of the median lobe.

Colour of pterothoracic sterna of adults is predominantly yellow in all specimens seen. Some specimens become discolored by breakdown of fat body and other viscera but without exception these conform to the generalized pattern once thoroughly cleaned.

The majority of specimens of *D. circumcinctus* which I have seen from the Nearctic region are from western Canada and adjacent areas. Within these areas, there is some suggestion of a geographic pattern to relative frequency of elytral sulcation of females. For instance, of 309 females from Alberta, Manitoba, Northwest and Yukon Territories, Saskatchewan, and North Dakota, only 33 or 11% are sulcate. The number of specimens from other areas is much less, but of 28 females from Alaska, British Columbia, and Washington, 22 or 79% are sulcate.

Guignot (1932:722) and F. Balfour-Browne (1950:277) state that specimens of *D. circumcinctus* are rarely collected in France and Great Britain, respectively. Of those adult females collected, they mention that sulcate specimens are scarce. Guignot writes that sulcate specimens are more common in Sweden. Available information supports his claim: of 73 females from Sweden, 64 or 88% are sulcate, and of 87 females from Finland, 65 or 75% are sulcate. In these areas, *D. circumcinctus* is collected more commonly than it is in France and Great Britain. Interestingly, Zaitsev (1953:354) states that sulcate and non-sulcate females occur in about equal abundance in the U.S.S.R., but does not mention whether he noted a regional disparity in dimorphism. He also records it as the commonest species of *Dytiscus* in the U.S.S.R.

In summary, within the western portions of the Palearctic region, specimens of *D. circumcinctus* are more scarce southward, but of these, non-sulcate females make up a greater proportion. Within North America, there is a similar trend in abundance, but most records of non-sulcate females are from east of the Rocky Mountains, with sulcate females predominating to the west. These trends are only preliminary, but suggest differences in dispersal rates and sources of fauna (e.g. western Nearctic populations may be derived from the Russian fauna via Beringia), or of physiological-genetic properties of non-sulcate females, or a combination of both features. Further information and investigation is warranted to achieve better understanding of the pattern.

*Natural history.*— Most of the comments presented below refer to my own collecting experiences in western Canada, label information from specimens examined, and some literature references. As more detailed collecting notes, natural history studies, larval identification and similar types of information become available, they will provide an interesting and informative comparison against, in particular, the seeming structural uniformity of adult *D. circumcinctus* throughout its range.

Larson (1975:402) noted the broad range of habitats in which he had collected adults of *D. circumcinctus* within Alberta. My experience suggests that this observation is true for most of western Canada, and can extend Larson's range of habitats to highly alkaline or saline habitats. Galewski (1971b)

similarly recorded a wide ecological valence for this species in Poland as does Borchert (1938:17) for Germany; Borchert (1938) describes this species as scarce and sparsely distributed. However, Guignot (1932:722) implies that, in France, *D. circumcinctus* is restricted to cold clear aquatic habitats, and F. Balfour-Browne (1950:278) records it primarily as a locally distributed inhabitant of fens in Britain. In Sweden it is found primarily in eutrophic, lowland lakes (Nilsson, pers. comm). A wide habitat range would provide an adaptive advantage for this species, and presumably forms part of the reason for its Holarctic distribution pattern. Nevertheless, in certain areas, such as France and Great Britain, habitat diversity of *D. circumcinctus* may be curtailed by any number of features (e.g. local competition).

Galewski (1964) records a specimen of *D. circumcinctus* being taken from forest litter in Poland during winter. An adult male that I collected in Edmonton, Alberta on 23.v.79 was under a log on the south shore of the North Saskatchewan River ravine. Each year, this north-facing slope near the river is one of the last areas to lose snow cover, and temperatures are kept low because of the nearby ice on the river. Therefore, I suspect that this specimen overwintered at that particular site. Larson (1975:402) reported taking specimens through the ice in February. Thus, these few preliminary data suggest that adult specimens of *D. circumcinctus* may overwinter either on land or in water.

Galewski (1971b) discusses early season occurrence of this species in temporary pools where it feeds extensively before moving on to more permanent habitats for reproduction. Available flight records (Table 5 and Larson 1975) suggest one peak of dispersal in April and May and another in September and October. The majority of teneral specimens seen by Larson (1975) were from July, and in Table 4 there is one each for May, June, August and September. This variation may well indicate local topographic differences in habitats, such as availability of prey, water temperatures, etc.

*Distribution (Figs. 42 and 43).*— This species is widespread within the Holarctic Region. In North America it is transcontinental, with records from Maine to Alaska. It occurs as far south as North Carolina, and I have taken it at tree-line in Canada's Yukon Territory. In the Palearctic region it ranges from Norway and Great Britain south to Italy (Franciscolo 1979:69) and Bulgaria (Guéorguiev 1958) and westward throughout the region. I have been unable to find records for Spain excluding the Pyrenees. Apparently it is collected less commonly in the southern portions of its range.

*Chorological relationships.*— In some parts of its range, *D. circumcinctus* is sympatric with every other species of *Dytiscus* except *D. habilis* in the Nearctic Region, and, in the Palearctic, *D. sinensis*.

*Phylogenetic relationships.*— Adults of *D. circumcinctus* possess acuminate metacoxal processes and therefore belong to one of the more advanced grades within *Dytiscus*. The median lobe is not sinuate laterally, but has an apical knob with sensory pores. These synapotypic character states define adequately the relative position of *D. circumcinctus*, but the exact sister group relationship of the species is less certain. The only character I could find to separate the more advanced members of this clade from *D. circumcinctus* is the relatively abrupt bend in the lateral ridge of the median lobe of advanced members, compared to the evenly curved lateral ridge of the same structure in members of *D. circumcinctus*. I believe this to be a relatively weak character, and thus the hypothesized sister group relationship may change as new characters are found and incorporated into the analysis. Members of *D. latissimus*, *D. alaskanus* and *D. circumcinctus* are very difficult to place in the cladogram. The

two former species probably have lost the apical knob of the median lobe secondarily.

*Material examined*.— A total of 1470 specimens of *D. circumcinctus* was examined: 283 males and 337 females from the Palearctic region, and 351 males, 381 females and 18 specimens of undetermined sex from the Nearctic region.

*Dytiscus alaskanus* J. Balfour-Browne, 1944

Figs. 5A, 12A, 19B, 22G, 44, and 52

*Dytiscus parvulus* Motschulsky 1852:77 (Lectotype male designated here, in UMHF, labelled as follows: LECTOTYPE; SYNTYPE; Kadjak; Holmberg; *Dytiscus parvulus*, Ménétr., Kadjak; LECTOTYPE, *Dytiscus parvulus* Motschulsky 1852, designated R.E. Roughley; *Dytiscus alaskanus* J.B.-B. det. R.E. Roughley 1982) *nec* Müller 1776:73. -Zimmermann 1920:253. -Hatch 1929:227. -Brown 1930:237. -Wallis and Larson 1973:110. Larson 1975:404.

*Dytiscus alaskanus* J. Balfour-Browne 1944:356. -Larson 1975:404.

*Dytiscus ooligobuckii*; J. Balfour-Browne 1948:161. -Gordon and Post 1965:25.

*Dytiscus ooligobuckii*; Hatch 1953:238.

*Dytiscus ooligobuckii*; Anderson 1962:73 *nec* Kirby 1837:74. -Larson 1975:404.

*Dytiscus ooligobuckii*; Kirby 1837:74. **Misidentification** of *D. circumcinctus*, *quod vide*.

*Derivation of specific epithet*.— The name of this taxon was proposed in honour of the State of Alaska, U.S.A., where it is abundant, and which contains the type locality of *D. parvulus*, for which *alaskanus* is a replacement name.

*Notes about type material*.— The type series of *D. alaskanus* in UMHF consists of six specimens: five males and one female. The female is non-sulcate. The type locality, Kodiak Island, is the western-most record I have for this species. All specimens have at least sterna II, III and VI with transverse dark fascia, and most, including the lectotype, have narrow markings on sterna IV and V.

*Diagnostic combination*.— Adults of *D. alaskanus* are known only from the Nearctic region. Only three species within the Nearctic region have acuminate metacoxal processes: *D. circumcinctus*, *D. alaskanus* and *D. dauricus*. Those specimens of *D. alaskanus* with a predominantly yellow venter are most easily separated from *D. circumcinctus* by absence of a yellow ring around the eye dorsally, by the fusion of inter-sulcal ridges apically on sulcate females (compare Figs. 4C and 5A). Specimens of *D. alaskanus* with fasciate abdominal sterna are most similar to specimens of *D. dauricus*, and are best separated by the characters presented in the key.

*Description*.— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 5A; coloration of pterothoracic and abdominal sterna in Fig. 12A; median lobe of male in Fig. 19B; and metacoxal processes in Fig. 22G.

*Taxonomic notes*.— Larson (1975:404) provides a detailed history of the long, confused history of the nomenclature of this taxon.

*Variation*.— Larson (1975:404) provides notes about variation of this taxon within the province of Alberta, and therefore I confine this discussion to other geographic areas to variation of some taxonomically important characters. Further discussion is provided in the treatment of *D. dauricus*.

Colour of pterothoracic sterna varies geographically. Most specimens of *D. alaskanus* observed from British Columbia, Newfoundland, Northwest and Yukon Territories have completely yellow venters, whereas the majority of specimens from intervening localities have at least some degree of infuscation.

The median lobe of males of all these specimens is similar to that shown in Fig. 19B.

Larson (1975:404) mentions only one Alberta locality, near the Northwest Territories border, for non-sulcate females, and in excess of 99% of our combined samples are sulcate. Throughout most of its range, females of *D. alaskanus* are consistently sulcate, and where non-sulcate females do occur, they make up only a very small proportion of the total. The areas for which I have seen non-sulcate females, and the percentage of the total number of females seen from that geographic area (localities for non-sulcate females in parentheses) are as follows: British Columbia - 5 of 56 or 9% (Kamloops area, Summit Lake, and Mile 627 on Alaska Highway); Manitoba - 3 of 13, or 23% (The Pas); Saskatchewan - 1 of 6, or 7% (Saskatoon); Ontario - 1 of 11, or 9% (Toronto); Colorado - 5 of 20, or 25% (Breckenridge and Science Lodge W., both in Summit Co.); Northwest Territories - 4 of 15, or 27% (Ft. Smith, Reindeer Depot, and Simpson Islands in Great Slave Lake); Alaska and Yukon Territory - 12 of 34, or 35% (Ft. Yukon, Kodiak and Fairbanks; Mile 629 and 681 on Alaska Hwy., Chappie Lake, Von Wilczek Lake, Watson Lake, and Whitehorse). As suggested by Larson (1975), this elytral form is more common in the northwestern position of the range of *D. alaskanus*. It is interesting, but as yet unexplained, that the co-occurring *D. circumcinctus* shows the reverse pattern over much of the same area (*i.e.*, non-sulcate form predominant southward). Low level occurrence of non-sulcate females in other widely separated areas such as Ontario and Colorado is perhaps associated with dispersal, but possibly also indicates independent loss of sulcation within these areas. None of the non-sulcate females is provided with label data giving precise habitat, and therefore the possibility of an ecophenotypic response cannot be ruled out.

*Natural history.*— Members of *D. alaskanus* are collected in very large numbers at various localities in western Canada. Many bottle traps left in George Lake, near Busby, Alberta, for two days yield 10 to 15 specimens per bottle, and have taken up to 80 specimens. Most localities where net-collecting has yielded only one or two specimens have produced many times this number when bottle traps were used subsequently. This confirms the observation made by Larson (1975) that adults are often numerically abundant at particular localities.

In northwestern North America, members of *D. alaskanus* have been collected from permanent ponds and lakes in prairie, aspen parkland and boreal forest. Specimens of *D. alaskanus* overwinter in bodies of water such as George Lake and are active quite early in the spring, often before the ice is off the lake. I have observed copulating pairs from mid-April to early June at this locality. Favoured oviposition sites are plants such as *Scirpus* and *Typha*. Held in captivity for a week to ten days, with a single plant available for oviposition, two or three females reduce a plant to shreds by constant slitting of the leaves and stem with the ovipositor. During this time, individual females lay up to 40 eggs within the plant tissue. It is not known whether females lay a similar number of eggs under field conditions, but the above number may be conservative, because availability and quality of oviposition sites, as well as quality of food is greater in the field than it is possible to provide in the laboratory.

Aiken (1985) discussed the correlation of life histories of the hydrachnellid mites (*Eylais* sp.) and *D. alaskanus*. Aiken (1986) and Aiken and Wilkinson (1985) provide a detailed life history of this species at George Lake, Alberta.

Larval development in natural conditions is probably dependent on amount and type of food available, and on water temperature. For instance, most teneral specimens were collected in August, but in seasonally more advanced and warmer areas such as Kamloops, British Columbia, teneral specimens were collected in late June (Table 4). Larson (1975) records a teneral specimen as late as mid-October.

Some dispersal occurs in spring (Table 5) and perhaps again in autumn. It is interesting that the number of flight records is so low, given local abundance of this species throughout its range.

*Distribution* (Fig. 44).— This species is transcontinental in North America with records from Newfoundland to Alaska. The southern limit of *D. alaskanus* is represented by an isolated population in south-central Wyoming and adjacent areas of Colorado. Most records are from south of tree-line, but some scattered records indicate possible extension onto tundra habitats.

*Chorological relationships*.— The range of *D. alaskanus* overlaps that of every other Nearctic species except *D. habilis* and *D. carolinus*.

*Phylogenetic relationships*.— As with *D. latissimus*, placement of *D. alaskanus* in the phylogenetic analysis is provisional because, in dorsal view, the median lobe of males of both species lack a distinct apical knob. In males of *D. alaskanus*, however, the knob is visible in ventral view, and therefore is most likely an example of reduction from the well differentiated state, unlike the condition of *D. latissimus*. Members of *D. alaskanus* and *D. dauricus* may represent a sister pair of species, but I have been unable to find a synapotypic character state linking them.

The more advanced members of *Dytiscus*, as shown in the cladogram, are united by having the median lobe of males sinuate laterally. This is a condition absent from *D. alaskanus*. The lack of an apical knob in dorsal view and the absence of lateral sinuation of the median lobe could be part of the same evolutionary step. A shortening of the apical portion of the median lobe may have brought about changes in both character states simultaneously.

*Material examined*.— A total of 661 adult specimens were examined and the label information recorded from these. Of these, 387 are males and 274 are females. In addition, long series of this species from George Lake, Alberta were examined but the label information not recorded. The total number of adult specimens examined is thus in excess of 2000.

#### *Dytiscus dauricus* Gebler, 1832

Figs. 5B, 12B, 19C, 22H, 45, 46, and 52

*Dytiscus dauricus* Gebler 1832:39 (Type area - "le district des mines de Nertschinsk, dans la Sibérie orientale". Lectotype male selected here from Marseul collection, MNHM, labelled as follows: LECTOTYPE; SYNTYPE; *Dytiscus Dauricus* Gebler, Sib. or. 62; *Dytiscus dauricus* Gebler, Sib. or.; [indistinguishable mark similar to "q"]; Lectotype, *Dytiscus dauricus* Gebler selected by R.E. Roughley). -Zimmermann 1920:247. -Hatch 1929:227. -Brown 1930:237. -Hatch 1933:11. -Zimmermann and Gschwendtner 1938:55. -Brinck 1946:154. -J. *Dytiscus frontalis* Motschulsky 1859:489. *Nomen nudum*. J. Balfour-Browne 1944:356.

*Dytiscus frontalis* Motschulsky 1860:101 (Type locality - "Kamtschatka", Alaska. Type not seen.) *nec* Marsham 1802. -Zimmermann 1920:248.

*Dytiscus vexatus* Sharp 1882:643 (Type area - Russian America. Type - see Larson 1975:403). - Zimmermann 1920:255.

*Dytiscus dauricus* var. *obscurus* Gschwendtner 1922:93 (Type locality - "Berisovka in Transbaikalien", USSR. Type not seen). Zimmermann and Gschwendtner 1938:56. - Zaitsev 1953:354.

*Dytiscus amurensis* J. Balfour-Browne 1944:356. New name for *D. frontalis* Motschulsky 1860 *nec* Marsham 1802.

**Derivation of specific epithet.**— Named for 'Dauria', a region in eastern Asia east of Lake Baikal (now divided between the U.S.S.R. and China), which includes the type locality.

**Notes about type material.** - Three sources of information were used as the basis for selection of the above lectotype of *D. dauricus*. First, a male specimen of *D. dauricus* in BMNH is labelled "Siberia; Sharp coll., 1905-313 [inverted label]; Siberia or. [inverted yellow label]; *Dytiscus dauricus* according to a type in de Marseul's coll." The last label is in David Sharp's handwriting. Second, Horn and Kahle (1935-1937) state that the collection of F.A. von Gebler was transferred to the René Oberthür collection in MNHM, as was that of S.A. de Marseul. Third, in de Marseul's collection is a box-label which reads "Communiqué à. M. Sharp par M. Lewis le 8 1876" and in the following list is the name *D. dauricus*. From this information, I have inferred that this specimen is part of Gebler's material and available for designation as lectotype.

**Diagnostic combination.**— In the Nearctic region adults of only *D. dauricus* and *D. alaskanus* possess acuminate metacoxal processes and fasciate abdominal sterna. Members of these two taxa are best separated by the characters presented in the key to adults of the Nearctic region. In the Palearctic region, *D. dauricus* occurs abundantly only about as far west as the Lake Baikal region, although there is one record for Yining (Kuldja), China at 43° 55'N 81°14'E. This distribution, in combination with fasciate abdominal sterna, and acuminate but not spinose metacoxal processes will separate members of *D. dauricus* from other congeners in this area.

**Description.**— Measurements of representative specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 5B; coloration of pterothoracic and abdominal sterna in Fig. 12B; median lobe of male in Fig. 19C; and metacoxal processes in Fig. 22H.

**Taxonomic notes.**— Larson (1975) discussed most of the taxonomic problems associated with *D. dauricus*. Many names have been proposed for this taxon, in part because in most collections it is represented by only a few specimens, and if the specimens are from widely separated geographic localities they may appear to represent different taxa, especially if characteristics of the male median lobe are excluded. Also, and perhaps correlated with the above, authors' concepts of this taxon have been communicated inadequately over the years, and this has led to confusion concerning the naming of specimens.

*Variation.*— As noted under the treatment of Measurements (see also Table 2), there is a wide range in total length and associated measurements. However, specimens collected by bottle trap (Table 1) show a consistent size and are on average larger than those collected with dip nets. This suggests a size bias associated with collecting technique. As more series of specimens collected by bottle-trap become available for study, it will be valuable to test them against net-collected specimens from the same geographic area.

The predominantly yellow pterothoracic and abdominal sterna are marked consistently with infuscation in the material at hand. The mode of this pattern is darker than that of *D. alaskanus*, but the variation shown in the latter eliminates ventral colour pattern as a useful taxonomic character, except on a regional basis. In certain geographic areas, population samples have a majority of specimens with, for instance, expanded infuscation of metathoracic 'wing' *e.g.* Fig. 12B left combined with more yellow abdominal sterna (*e.g.* Fig. 12B right). I have been unable to find a pattern in this variation, and indeed, there may not be one. In general, darker specimens predominate and increased infuscation of any one sternum is correlated positively with increased infuscation of other sterna.

An important feature unique to females of *D. dauricus* is the distinct disjunction between the planes of clypeus and frons at the fronto-clypeal suture. The frons is markedly recessed from the clypeus (Larson 1975:403). Some female specimens of *D. alaskanus* show a slight planar disjunction in this area, and this is marked in some teneral specimens. Once specimens of both taxa have been seen, however, the difference in degree is sufficient to allow reliable use of this character for separation of female members of these taxa.

Another character used to distinguish among females of *D. alaskanus* and *D. dauricus* is arrangement of the inter-sulcal ridges of the apex of the elytron. Character state differences are presented in couplet 13 of the key to Nearctic species. I have seen no exceptions to this dichotomy, except where elytra have been malformed, presumably during eclosion from the pupal cell.

Of the 41 female specimens seen from the Palearctic region, 13, or 32%, show no trace of elytral sulci, 27 are distinctly sulcate, and one specimen has the sulci only slightly impressed. From the Nearctic region, 315 specimens were available for analysis. Distribution of sulcate and non-sulcate females from North American localities is given in Table 6. These data are presented in a northwest to southeast direction. While it will be more compelling when more specimens become available for study, these preliminary numbers suggest three areas of occurrence of non-sulcate females: 1, Alaska, Yukon and Northwest Territories, Ontario, and the western Provinces of Canada; 2, Newfoundland; and 3, high altitude sites in Colorado and Wyoming. These localities are just as suggestive of development of the non-sulcate form in refugia (*i.e.*, Beringia, Newfoundland, and alpine Colorado and Wyoming) as they are of environmental influence on proportion of non-sulcate females. The latter scenario is somewhat weakened when it is considered that samples of *D. dauricus* from presumably similar habitats in California, Idaho, Montana, Nevada and Utah contained no non-sulcate female specimens. Both hypotheses are weakened by the low proportion of non-sulcate females in Alaska and Yukon Territory.

*Natural history.*— Larval development of *D. dauricus* is completed by late July to early August in Alberta and Minnesota, as teneral specimens from the first half of August were seen by Larson (1975) and me (Table 4). This species seems to prefer permanent pond or lake habitats, and these are usually associated with some amount of tree cover (Larson, 1975).

Further north in its range, *D. dauricus* occurs at a broad range of altitudes including sea level. Further south in its Nearctic range, at least, it becomes restricted to higher elevation. Blake (1945) recorded *D. dauricus* from large permanent and moraine ponds at 3050 and 4011 m in the Medicine Bow Mountains of Wyoming. Holomuzki (1986) found specimens of this species only at elevations above about 2500 m in the White Mountains of Arizona. *Dytiscus dauricus* is sympatric with *D. marginicollis* in Arizona but Holomuzki (1986) reports that, among his study sites, *D. marginicollis* was found from 1500 to 2500 m whereas *D. dauricus* was found only at higher elevations.

Holomuzki (1985) discussed the life history of *D. dauricus* in east central Arizona where they are predators of larval tiger salamanders, *Ambystoma tigrinum nebulosum* (Ambystomatidae) (Holomuzki 1986). Blake (1945) observed mating in the first week of July at his high elevation study site in Wyoming.

Available flight records are for April, July, September and October (Larson, 1975, and Table 5). This species may overwinter in the permanent habitats which they inhabit because specimens were caught in bottle traps at George Lake near Busby, Alberta in late April, 1982, when the margins of the lake were ice-free, but most of the lake was still frozen. At this locality, *D. dauricus* occurs at a much lower density than does *D. alaskanus*; however, in Arizona Holomuzki (1986) estimated an abundance of 2.6 adults/m<sup>3</sup>.

*Distribution* (Figs. 45 and 46).— This Holarctic species ranges from Newfoundland westward to Alaska, and occurs sporadically on the Aleutian Islands. In North America, most localities are from south of tree-line, but certain localities in northern Labrador, Ontario and Manitoba probably indicate that it occurs in tundra ponds. The range of *D. dauricus* extends southward along the western mountain ranges to Arizona and California and may occur in alpine and sub-alpine ponds in these areas. In the Palearctic region, most records are from east of Lake Baikal. The most southern and western record is for Yining, China.

*Chorological relationships*.— In North America, this species is sympatric with every other Nearctic species except *D. habilis* and *D. carolinus*. In the Palearctic it is sympatric with *D. sharpi*, *D. marginalis czerskii*, *D. delictus*, *D. circumcinctus*, *D. lapponicus lapponicus*, *D. latro* and possibly *D. latissimus*.

*Phylogenetic relationships*.— The robust form and markedly curved lateral margins of the median lobe of males of *D. dauricus* indicate close relationship of this taxon to *D. lapponicus*, *D. circumflexus*, *D. thianshanicus*, *D. latro* and *D. sinensis* (Fig. 52). Unlike these taxa, however, adults of *D. dauricus* do not have a spinose metacoxal process.

*Material examined*.— A total of 768 adult specimens of *D. dauricus* was examined. From the Palearctic region were 27 males and 41 females, and from the Nearctic region, 382 males and 336 females.

*Dytiscus lapponicus* Gyllenhal, 1808  
Figs. 5C, 12C,D, 19D,E, 22I,J, 47, and 52

*Dytiscus lapponicus* Gyllenhal 1808:468.

*Derivation of specific epithet*.— Latin, referring to the type locality, Lapland.

*Diagnostic combination*.— The combination of Palearctic distribution, acuminate metacoxal lobes, pronotum with very broad yellow margins on all sides and elytra predominantly yellow with rows of black dots easily distinguish members of *D. lapponicus*.

*Taxonomic notes.*— I have arranged *D. lapponicus* in two subspecies: widespread nominate subspecies, and another restricted to the Italian Alps, for which the subspecific epithet *disjunctus* is available. The form of the median lobe of both subspecies is quite similar but there is a major difference in coloration of the prothoracic disc in the material I have seen (see couplet 13 of key to Palearctic species). I have chosen to treat these named forms as subspecies because: 1, they are allopatric; 2, other specimens of *D. lapponicus* from latitudes near or as far south as that of *D. disjunctus* (e.g. France, Germany and U.S.S.R.) do not exhibit its characteristics; and 3, distinctiveness of both groups judging from specimens I have seen. On the basis of colour characteristics studied, each specimen was assigned easily to one or the other subspecies, and subsequent use of geographic criteria showed this to be correlated. Other colour characteristics of *D. lapponicus disjunctus* not used in the key but perhaps correlated with reduced infuscation of the pronotum are greatly expanded yellow band around eye (more than 0.5 width of eye) and posterior extension and expansion of chevron such that it appears hour-glass shaped but with anterior portion wider. Other character differences are discussed by Zimmermann and Gschwendtner (1938:50).

Many Palearctic authors have commented on this form and most have suggested it to be an aberration. Below, I present a brief, selected history of the taxonomic treatment of this form.

Seidlitz (1887:111) accepted *D. disjunctus* as valid at the level of species. Zaitzev (1908) states that recognition of the form *disjunctus* as an alpine "race" is unjustified because he had seen specimens with similarly coloured pronota from northern Russia. Holdhaus (1912:423) states that *D. lapponicus* occurs in the typical or nominate form at La Grave, Isère (now in Dep't. Hautes-Alpes, France). Guignot (1932:726, 1947a:246) presents records for *D. lapponicus* ab. *disjunctus* from Meyrannes near Barcelonnette (Dep't. Basses-Alpes, France) and "lac du col de Lauzanier". Interestingly, Guignot, in the former reference, records La Grave as a locality for the nominate form (perhaps following Holdhaus, above) but in later work suggested it as a locality for ab. *D. disjunctus* without providing an explanation for the change. Brundin (1934:252), citing earlier authors, gives, in addition, records for Mt. Cenis (Dep't. Savoie, France) and Simplon (Canton Valais, Switzerland). All of these localities are relatively close to the type locality of *D. lapponicus disjunctus*, but are on the northern and southwestern portions of the watershed of the Alps, whereas the type locality of *disjunctus*, Lago della Magdallena, is on the southern portion of the watershed. Re-examination of these specimens is very important. Because of the problems associated with the Guignot records, I have treated them all as belonging to the nominate subspecies. Also, I do not believe that the concept of this taxon has been well communicated among coleopterists within the region; specimens are not numerous and are restricted to only a few museums. I believe that area of collections was used previously for determination, rather than other characters. If these records do represent the nominate subspecies, then they must represent dispersal records from other areas (e.g. Germany) or at least be remnants of a different colonization of the Alps from that which gave rise to *D. lapponicus disjunctus*.

Zimmermann (1919:233) and Zimmermann and Gschwendtner (1938:50) cite *D. disjunctus* as an example of an inbred "race" formed by extreme geographic isolation. F. Balfour-Browne (1950:238) suggests that the main diagnostic feature of *D. disjunctus* is fragmentation of the pronotal infuscation and that Scottish specimens of the nominate form showed evidence of an

"elementary stage" of development of this character state. Therefore, he judged *D. disjunctus* to represent a simple aberration. Zaitsev (1953:329) states that *D. disjunctus* is a psychophilic form as he has seen specimens from Leningrad. I have not seen Zaitsev's specimens. As stated above, the paucity of available specimens may have influenced Balfour-Browne's and Zaitsev's concepts of *D. lapponicus disjunctus*. If they believed that it is only characterized by fragmentation of the infuscated portion of the pronotal disc, then they could have been misled by variation within *D. lapponicus lapponicus*.

The infuscated portion of the pronotum of specimens of the nominate subspecies varies in width, situation and fragmentation, but I have seen no extralimital specimens showing character states similar to that of members of *D. lapponicus disjunctus*. Furthermore, even if this character state is demonstrated to occur in other populations, it cannot be inferred that subspecies status is invalid - only that further analysis and characters are needed.

*Distribution* (Fig. 47).— This is a species of more northern distribution than other Palearctic species. It occurs sporadically in southern Europe, usually associated with montane, or at least cold, oligotrophic habitats. It is more common in northern Europe and is known from throughout the U.S.S.R. I have seen no reliable records for North America.

*Chorological relationships*.— Areally, the combined range of both subspecies suggests sympatry with most Palearctic species except *D. sharpi*, *D. persicus* and *D. sinensis*, and possibly *D. delictus*. Differences in preferred habitat suggest that co-occurrence within habitats (or effective sympatry) could happen with *D. marginalis*, *D. circumcinctus*, *D. dauricus*, *D. latro* and *D. thianshanicus*.

*Phylogenetic relationships*.— Acuminate metacoxal processes, sinuate lateral margins of median lobe of male, with distinct sensory-type pores on apical knob indicate close affinity with *D. thianshanicus*, *D. latro* and *D. sinensis* (Fig. 52).

### *Dytiscus lapponicus lapponicus* Gyllenhal 1808, NEW STATUS

*Dytiscus lapponicus* Gyllenhal 1808:468 (Type area - "habitat in aquis Lapponiae". Type not seen). -Zimmermann 1920:248. -Guignot 1932:48. -Houlbert 1934:134. -Zimmermann and Gschwendtner 1838:34. -F. Balfour-Browne 1953:27. -Zaitsev 1953:351. -Schaefflein 1971:88.

*Dytiscus borealis* Motschulsky 1860:101 (Type area - "Sibérie". Type not seen.).

*Dytiscus septentrionalis* Gyllenhal 1827:373 (Type area - "Habitat in Finlandiae aquis". Type material - see Notes, below.).

*Dytiscus lapponicus* var. *septentrionalis*. **Unjustified emendation**. -Zimmermann 1920:249. -Guignot 1932:723. -Houlbert 1934:134. -Zimmermann and Gschwendtner 1938:48. -F. Balfour-Browne 1950:280. -F. Balfour-Browne 1953:27. -Zaitsev 1953:351. -Schaefflein 1971:88.

*Notes about type material*. — Type material of *D. septentrionalis* was examined from the Gyllenhal collection in Riksmuseet, Stockholm. There is a male specimen labelled "Finlandia, Falander, ♂ in copula; Coll. Sahlberg" and a female specimen labelled "Finlandia, Falander, ♀ in copula; Coll. Sahlberg". Other notes associated with these specimens are "septentrionalis, Germ. in litt., lapponicus var B Gyll. Ins. Sve.; *Dytiscus septentrionalis*, Gyllenhal Ins. Sve. IV app. p. 373 3-4, Habitat in Finlandiae aquis rarius, a Dom Vasastjerna in copula captus; Mus. Dom. Schönherr." These specimens are syntypes but I did not label them as such nor did I designate a lectotype.

*Diagnostic combination.*— The broad pronotal infuscation and distribution which excludes the Italian Alps, in conjunction with the diagnostic combination of the species, are sufficient to identify adult members of *D. lapponicus lapponicus*.

*Description.*— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 5C; coloration of pterothoracic and abdominal sterna in Fig. 12C; median lobe of male in Fig. 19D, E; and metacoxal processes in Fig. 22I.

*Variation.*— This is a relatively varied taxon, but the limits are defined and identification is usually easy because of several unique features. With respect to diagnostic features, pronotal infuscation is somewhat varied (see Taxonomic notes under *D. lapponicus*). The width of this infuscation is at most subequal to that of the width of an anterior or posterior yellow band. The anterior and/or posterior margins of the band are sinuate in some specimens. Some specimens have the pronotal infuscation arranged in three or more blocks by longitudinal incursions of yellow.

F. Balfour-Browne (1950:281-282) noted the trend for more northern samples of *D. lapponicus lapponicus* to have a greater proportion of non-sulcate females than more southern populations. Unfortunately, he does not provide relative proportions of sulcate and non-sulcate females for the Scottish and Irish samples that he studied. Other available data also suggest this trend. Guignot (1932:726) states that the non-sulcate form does not occur in France. Horion (1941:439-440) does not mention the varietal name used for non-sulcate females (as he does for other species with dimorphic females) as occurring in Germany, although I have seen a few specimens of ungrooved females labelled only "Germania". Of 28 female specimens seen from Prussia and Poland, all are sulcate. From Sweden, I have seen 71 females of which 54 or 76% are sulcate; from Finland, 105 females of which 84 or 80% are sulcate; and from Norway, 4 of the 11 or 36% of the females studied are sulcate.

As noted elsewhere (e.g. *D. alaskanus*), the cause of geographic variation in proportion of the two types of females is unknown. The pattern suggests dispersal from particular refugia, but ecophenotypic phenomena cannot be ruled out, nor can a combination of both. The observation that all females of *D. lapponicus lapponicus* are sulcate even though they occupy cold, oligotrophic habitats in the Alps argues against the hypothesis of ecophenotypic expression. Further detailed information of occurrence and relative proportion of both states would be most helpful in attempting an explanation.

*Natural history.*— What is known of the natural history of this species is summarized adequately by F. Balfour-Browne (1913, 1950:283-284) and Jackson (1955:84-85); Eriksson (1972) discusses aspects of the life history of this species in Finland as do Brinck and Wingstrand (1949, 1951) in Sweden.

*Distribution* (Fig. 47).— Very locally distributed in high mountains of southern Europe, with sporadic records for Germany, Switzerland, Holland, Belgium, Scotland and Ireland. Poppus (1910:356) discounts previous records of this species from Iceland. I have seen the following records which I believe to represent incorrect labelling: "Hongric [ongrie], Roussel" (2 CASC, 1 HHNM), Spain (2 ICCM), and Sitka (1 MNHN). There are no recent nor reliable records for North America.

*Material examined.*— A total of 657 adult specimens was examined, of which 259 were males and 657 were females.

*Dytiscus lapponicus disjunctus* Camerano 1880, NEW STATUS

*Dytiscus lapponicus* var. *disjunctus* Camerano 1880:120 (Type locality - Argentara, Piemonte, Italy. Type not seen.). Zimmermann 1920:249. -Gschwendtner 1923:110. -Guignot 1932:726. -Zimmermann and Gschwendtner 1938:48. -F. Balfour-Browne 1950:280. -Zaitsev 1953:351. -Franciscolo 1979:667.

*Derivation of specific epithet.*— Presumably, Camerano proposed this name to reflect the isolation of this taxon within the Italian Alps.

*Diagnostic combination.*— Reduction of pronotal infuscation to a sinuate line across the pronotal disc and restricted range, in conjunction with the diagnostic combination for the species, are sufficient to identify adult members of *D. lapponicus disjunctus*.

*Description.*— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is not shown (see Franciscolo 1979:658, Fig. 2046); coloration of pterothoracic and abdominal sterna in Fig. 12D; median lobe of male not shown; metacoxal processes in Fig. 22J.

*Variation.*— Shape of pronotal markings of specimens of *D. lapponicus disjunctus* examined is relatively consistent and similar to that illustrated by Franciscolo (1979:658, Fig. 2046).

All of the 38 females seen are sulcate.

If fresh material can be obtained (but see natural history), it would be useful to determine whether or not flight muscles are present within members of this subspecies. Jackson (1955) suggested that absence of flight muscles from Scottish specimens of the nominate subspecies could have played a role in the limited distribution of that form in Scotland.

*Natural history.*— Most collection records have no dates associated with them. Available dates are: vii.1898, vii.21, 8.viii.21, viii.23, 22.viii.23. These correlate well with those mentioned by Franciscolo (1979), who further states that he has been unable to collect this subspecies at the type locality despite repeated attempts since 1954. Intensive collecting by Franciscolo and others has failed to find any other localities for *D. lapponicus disjunctus*. Franciscolo correlates the demise of this taxon with the introduction of trout into the type locality and similar lakes within the Italian Alps. This is very interesting, because F. Balfour-Browne (1913, 1950) mentions that in Scotland *D. lapponicus* is taken only in lochs from which trout are absent. Franciscolo mentions that trout could have preyed upon the immature forms of this subspecies and that it may already be extinct.

*Distribution* (Fig. 47).— All specimens that I have seen were labelled with part of the following compounded label information: Lago della Maddalena, Argentera, Col de Larche, Valle Sture, Piemonte, Alpi Marittime, 2000 m. Other possible records are treated under Taxonomic notes for *D. lapponicus*.

*Material examined.*— A total of 50 adult specimens was examined, 12 males and 38 females.

*Dytiscus circumflexus* Fabricius, 1801

Figs. 5D, 13A, 20A, 22K, 48, and 52

*Dytiscus circumflexus* Fabricius 1801:258 (Type area - Tanger *vide* Guignot 1961:860. Type not seen.). -Zimmermann 1920:245. -Müller 1926:299. -Guignot 1932:722. -Houlbert 1934:135. -Zimmermann and Gschwendtner 1938:51. -Guignot 1947a:245. -F. Balfour-Browne 1950:273. -F. Balfour-Browne 1953:27. Zaitsev 1953:351. -Guignot 1961:860. -Schaefflein 1971:88. -Franciscolo 1979:669. -Régil and Salgado 1984:133,135.

- Dytiscus flavomaculatus* Curtis 1826:99 (Type area - not known to me. Type not seen.). - Zimmermann 1920:246.
- Dytiscus flavoscutellatus* Latreille 1806:331. (Type area - not known to me. Type not seen.). - Zimmermann 1920:246.
- Dytiscus excrucians* Stephens 1828:503 (Type area - not known to me. Type not seen.). - Zimmermann 1920:246.
- Dytiscus dubius* Serville 1830:90 *nec* Gyllenhal 1827:373 (Type area - near Paris, France. Type not seen.). - Zimmermann 1920:246.
- Dytiscus circumflexus* var. *dubius* Serville. - Zimmermann 1920:246. - Müller 1926:299. - Guignot 1932:722. - Houlbert 1934:135. - Guignot 1947a:245. - F. Balfour-Browne 1950:273. - F. Balfour-Browne 1953:27. - Zaitsev 1953:351. Guignot 1961:860. - Schaefflein 1971:88. - Franciscolo 1979:669.
- Dytiscus perplexus* Boisduval et Lacordaire 1835:302 (Type area - near Paris, France. Type not seen.). - Zimmermann 1920:246.
- Dytiscus pisanus* var. *kunstleri* Peytoreau 1894:xlII (Type area - not specifically stated, but probably near Bordeaux, France. Type not seen.). - Zimmermann 1920:246.

*Derivation of specific epithet.*— From Latin *circum* meaning "around" and *flexus*, meaning a "bending or turning". The significance of this epithet is unclear to me (perhaps a reference to the frontal chevron).

*Notes about type material.*— I have not seen the types of any of the various names applied to this species. Therefore, assignment of the names follows traditional usage (e.g. Zimmermann 1920). Explanation of Peytoreau's var. *kunstleri* is required. Most Palearctic workers such as Zimmermann have treated this name as if it were assigned species level status. This may be because these authors had not seen the original description published in a little known journal that is difficult to obtain. After reading the original description, I was unsure whether Peytoreau had described a specimen of *D. pisanus* or *D. circumflexus*. Reference to Peytoreau's figure of metacoxal processes definitely indicates the latter, as the processes are much too aciculate for members of the former.

*Diagnostic combination.*— All but four of the specimens examined have maculate abdominal sterna. This, in combination with acuminate metacoxal processes and principally European and North African distribution, should allow easy separation of most specimens. For specimens difficult to identify using external features, reference to features of the median lobe of males is essential, and females are best determined by association with males from the same region.

*Description.*— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 5D; coloration of pterothoracic and abdominal sterna in Fig. 13A; median lobe of male in Fig. 20A; and metacoxal processes in Fig. 22K.

*Taxonomic notes.*— This species is the most varied in body shape, yet the form of the apex of the median lobe is quite constant. Far eastern Palearctic records of this species probably result from confusion with *D. sinensis*, which is quite similar in markings of the venter.

The species *D. circumflexus*, *D. thianshanicus*, *D. latro* and *D. sinensis* comprise a monophyletic group of some complexity. As presently interpreted, they form a geographical replacement series extending through the Palearctic Region, basically from west to east, the taxa in the sequence indicated above. Of these four species, *D. circumflexus* (except as noted under variation) and *D. sinensis* are similar in ventral colour pattern (i.e., pterothoracic and abdominal sterna fasciate), while specimens of *D. thianshanicus* and *D. latro* have most of the venter yellow. The best characters for their separation are details of the form of the median lobe of males. Scanning electron micrographs of the apical

portions of the median lobe of male specimens are presented in Figs. 20A-D. Taxonomically important character states of the median lobe for each species are as follows: 1, shape of posterior portion of knob in ventral view - notched (*D. circumflexus*), triangularly extended posteriorly and fading into the ventral ridge (*D. thianshanicus* and *D. sinensis*), or evenly truncate (*D. latro*); 2, width of apical knob relative to that of preapical portion - knob much narrower than preapical portion (*D. circumflexus* and *D. thianshanicus*), and knob somewhat narrower than preapical portion (*D. latro* and *D. sinensis*); 3, prominence of apical knob in lateral view - not very prominent (*D. circumflexus*, *D. thianshanicus* and *D. latro*), and very prominent or spatulate (*D. sinensis*); 4, widening of ventral ridge in ventral view - abruptly (*D. circumflexus*) or evenly tapered (*D. thianshanicus*, *D. latro* and (*D. sinensis*); 5, in lateral view, the relative width of dorsal and ventral portions of median lobe just anterior to its greatest width (using lateral ridge as a dividing line) - dorsal portion much narrower than ventral portion (*D. circumflexus* and *D. thianshanicus*), dorsal and ventral portions approximately equal (*D. latro*), and dorsal much wider than ventral portion (*D. sinensis*).

*Variation*.— Specimens of this species exhibit a great deal of variation in body shape or habitus. This may be part of the reason for proposal of many of the names listed above. For instance, most male specimens have pronota wider than elytra and most females have pronota equal or subequal to elytra at the base. However, some males have pronota only as wide as that of most females, and some females have very narrow pronota so that the pronotal-elytral juncture appears emarginate. Such differences in pronotal shape drastically alter overall appearance of specimens. These characters are consistent within many local populations, but population samples from surrounding areas may show opposite extremes.

Most specimens have the venter marked with black (Fig. 13A left). However a few specimens have a completely yellow venter (e.g. from Sweden (Skåne), Czechoslovakia (Moravia), Hungary (Kolocsa), and Iran). There is little geographic correlation to this pattern except that the atypical specimens occur along the eastern edge of the range, although specimens with a typical pattern are found at the western-most locality in Afghanistan.

In Europe, excluding Great Britain, most female specimens are not sulcate. Scattered records of sulcate females are available for Sweden, France, Holland, Germany, Prussia or Poland, Corsica and Crete, as well as the Ahaggar Mountains of Algeria. In Great Britain, F. Balfour-Browne (1950:274) states that sulcate females predominate. Thus the trend is for more northern samples to be sulcate, whereas more southern samples are predominantly non-sulcate, and the most southern (but montane) samples are also sulcate.

*Natural history*.— A summary of the natural history of this species is presented by F. Balfour-Browne (1950:272-277), Alfes and Bilke (1977:104), and Aguesse and Bigot (1959). On the Iberian Peninsula, Régil and Salgado (1984:136) record it from altitudes ranging from 750 to 1250 m with most records of capture distributed from March to November with the latter predominant.

*Distribution* (Fig. 48).— All specimens of *D. circumflexus* that I have seen are from Europe, northern Africa and Asia Minor. Extralimital to Fig. 48 are records from various localities in the Ahaggar Mountains of southern Algeria. More eastern records (e.g. Siberia, by Zaitsev 1953:329) probably refer to *D. latro* and records for Kazakhstan (e.g. Konev 1976) need to be re-examined in light of the previously inadequately understood *D. thianshanicus*. Records of *D.*

*circumflexus* for the Canary Islands (F. Balfour-Browne 1950:276) need to be confirmed.

*Chorological relationships.*— Until the eastward extension of the range of *D. circumflexus* is better defined, it is difficult to list the taxa with which this species is sympatric. Within Europe, it is sympatric with *D. semisulcatus*, *D. mutinensis*, *D. dimidiatus*, *D. pisanus*, *D. marginalis*, *D. latissimus*, *D. circumcinctus* and *D. lapponicus*. It may be sympatric with *D. persicus* in Iran, but more records are needed to establish this with certainty.

*Phylogenetic relationships.*— *D. circumflexus* (if its distribution pattern is confirmed as suggested above), *D. thianshanicus* (south-central U.S.S.R., Afghanistan and Kashmir), *D. latro* (Siberia) and *D. sinensis* (northern China) seem to form a stepwise pattern suggesting vicariance and/or ecological replacement. This is supported by phylogenetic analysis (Fig. 52). These four taxa are united by common possession of a well-developed constriction of the apex of the median lobe just before the apical knob (Figs. 20A-D, dorsal view), and share with their sister group (*D. lapponicus*) very elongate metacoxal processes.

*Material examined.*— A total of 546 adult specimens of *D. circumflexus* was seen. Of these, 216 were males and 229 were females. Sex was not determined for one specimen.

#### *Dytiscus thianshanicus* Gschwendtner, 1923

Figs. 5E, 13B, 20B, 22L, 49, and 52

*Dytiscus thianshanicus* Gschwendtner 1923:107 (Type locality - "Aksu-Tal am Südabhang des Thian-schan" = Jachsu River Valley, Kuljab district of Tadzik S.S.R. Holotype male in OLML labelled as follows: Prov.Kuliab, Ak-sou-Thal; Type, Gschw.; Coll., Gschwendtner; Macrodytes, thianshanicus, Gschw.). -Zimmermann and Gschwendtner 1938:53. -Zaitsev 1953:352.

*Dytiscus latro*; Brancucci 1981:184, nec Sharp 1882:644.

*Notes about type material.*— The genitalia of the holotype are dissected and mounted on a card beneath the specimen as are the last two visible abdominal sterna. Study of the holotype of this species has altered my concept of it. Previously, all specimens assigned to this name by me were predominantly yellow on the ventral surface. The colour of the ventral surface of the holotype is illustrated in Fig. 13B and it is broadly marked with infusate areas.

*Derivation of specific epithet.*— Derived from the name of the mountain range in which the type locality is located.

*Diagnostic combination.*— A combination of south-central Palearctic distribution, spinose metacoxal processes, lack of narrow yellow ring around eye, and distinctive form of apex of median lobe of males distinguish members of this species.

*Description.*— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 5E; coloration of pterothoracic and abdominal sterna in Fig. 13B; median lobe of male in Fig. 20B; and metacoxal processes in Fig. 22L.

*Taxonomic notes.*— This species is still inadequately known. Members of *D. thianshanicus* are difficult to separate from those of *D. latro* except on the basis of form of the apex of the median lobe and distribution. The latter feature is of doubtful value, for ranges of both taxa are inadequately known. See also

taxonomic notes under *D. circumflexus*. I have re-examined the specimens determined as *D. latro* by Brancucci (1981) and assign them to *D. thianshanicus*.

*Variation*.— Too few specimens were seen to establish whether or not there are geographic patterns of variation. No sulcate females were seen but this may be due to the small number of specimens studied. Similarly as noted above in the discussion of type material, the colour of the ventral surface appears to be highly varied in this species, if indeed, all specimens belong to a single taxon.

*Natural history*.— I can find nothing published about natural history of this species, nor does the scanty label data supply any information.

*Distribution* (Fig. 49).— I have seen specimens only from south-central U.S.S.R. and from Afghanistan and Kashmir; however the locality from Kashmir (Tangmarg Pir Panjal Gebirge, 2400 m, 21-25.v.76) is extralimital to Fig. 49.

*Chorological relationships*.— This species is known to be sympatric (but see above) with *D. marginalis marginalis*, *D. circumcinctus* and *D. latissimus*. It may also be sympatric with *D. semisulcatus*, *D. persicus* and *D. dauricus*.

*Phylogenetic relationships*.— See similar section in treatment of *D. latro* and Fig. 52.

*Material examined*.— A total of 11 specimens of *D. thianshanicus* was examined and of these 7 were males and 4 were females.

### *Dytiscus latro* Sharp, 1882

Figs. 6A, 13C, 20C, 22M, 50, and 52

*Dytiscus latro* Sharp 1882:644 (Type locality - "Mantchuria". Holotype non-sulcate female in BMNH labelled as follows: Type [circular orange-rimmed label]; Mantchuria; Sharp Coll. 1905-313 [label inverted]; *Dytiscus latro*, Sharp type; Mantchuria Mus. Castelnau 948; HOLOTYPE, *Dytiscus latro* Sharp, examined R.E. Roughley 1981.). -Zimmermann 1920:249. -Zimmermann and Gschwendtner 1938:53. -J. Balfour-Browne 1946:453. -Zaitsev 1953:353.

*Dytiscus piceatus* Sharp 1882:644 (Type locality - "Eastern Siberia; (Irkutsk)". NEW SYNONYMY. Holotype male in BMNH labelled as follows: Type [circular orange-rimmed label]; Irkutsk, Siberia; Sharp Coll. 1905-313 [label inverted]; *Dytiscus piceatus*, Sharp type; Irkutsk, Siberia, 949; HOLOTYPE, *Dytiscus piceatus* Sharp, examined R.E. Roughley 1981). -Zimmermann 1920:253. -Zimmermann and Gschwendtner 1938:52.

*Dytiscus stadleri* Gschwendtner 1922:93 (Type locality - "Berisovka, Transbaikalien". Holotype male in ZSBS labelled as follows: "Type; [illegible handwriting, perhaps = Berisovka]; HOLOTYPE, *Dytiscus stadleri* Gschwendtner). -Zimmermann and Gschwendtner 1938:53. -J. Balfour-Browne 1946:453.

*Derivation of specific epithet*.— Latin *latro* means hireling, robber or brigand. The significance is not known.

*Diagnostic combination*.— A combination of eastern Palearctic distribution, predominantly yellow venter, spinose metacoxal processes, lack of narrow yellow ring around eye and distinctive form of apex of median lobe of males should adequately distinguish members of this species.

*Description*.— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 6A; coloration of paterothoracic and abdominal sterna in Fig. 13C; median lobe of male in Fig. 20C; and metacoxal processes in Fig. 22M.

*Taxonomic notes*.— The taxonomic problems associated with *D. latro* are a result of inadequate description (and therefore limited dissemination of Sharp's concept), association of sexes, and too few available specimens. The last feature remains the most critical. Sharp may have suspected that *D. latro* and *D. piceatus*

were representative of the same taxon, but does not clearly state this. Gschwendtner would have had difficulty assigning his specimen to *D. latro* based on the original description, and therefore described *D. stadleri*. Either he or Zimmermann noticed the error and provided the synonymy, although this is not clearly indicated in their publication, nor are their reasons for synonymizing them.

Sharp discussed both *D. latro* and *D. piceatus* on the same page of his monograph but *D. latro* occurs first, and is thus the valid name for this taxon.

Based primarily on the form of the median lobe of the male, this species appears distinct. Assignment of females is more difficult because of their similarity to females of *D. thianshanicus*. The most reliable means I have found is association with males and distributional differences. More specimens need to be examined before the present arrangement is treated as more than provisional.

*Variation*.— Too few specimens were seen to establish whether or not there are geographic patterns of variation. No sulcate females were seen, but this may be due to the small number of specimens seen.

*Natural history*.— I can find nothing published about the natural history of this species, nor does the scanty label data supply any information.

*Chorological relationships*.— The entire range of this exclusively east Palearctic species is known insufficiently. However, it is known or inferred to be sympatric with *D. sharpi*, *D. marginalis czerskii*, *D. delictus*, *D. circumcinctus*, *D. lapponicus lapponicus* and *D. latissimus*. Establishment of the western limits of *D. latro* and the eastern limits of *D. thianshanicus* would be helpful in determining the taxonomic status of these two taxa.

*Phylogenetic relationships*.— The sinuate lateral margins and well developed sensory pores on the knob of the median lobe of males, and spinose metacoxal processes indicate close relationship to *D. lapponicus*, *D. circumflexus*, *D. thianshanicus*, and *D. sinensis*. In Fig. 52, I have interpreted *D. latro* as the eastern vicar of the central Palearctic *D. thianshanicus*.

*Distribution* (Fig. 50).— This taxon occurs in the eastern U.S.S.R. (described loosely as Siberia) and adjacent Manchuria.

*Material examined*.— A total of 17 specimens was examined, of which four are males and 13 females.

#### *Dytiscus sinensis* Feng, 1935

Figs. 6B, 13D, 20D, 22N, 51, and 52

*Dytiscus sinensis* Feng 1935:182 (Type locality - Yin-Kuan-Tsai, Szechuen, China. Holotype male in USNM labelled as follows: Szechuen, CHINA, DC Graham; Yin-Kuan-Tsai, 12300 ft, vii.21.30; *Dytiscus sinensis* (Type) H.T. Feng). -Feng 1937:14. -Zimmermann and Gschwendtner 1939:27.

*Derivation of specific epithet*.— The specific epithet means Chinese.

*Diagnostic combination*.— A combination of eastern Palearctic distribution, fasciate abdominal sterna, spinose metacoxal processes, and spatulate form of apex of median lobe of males (in side view) distinguish adequately members of this species.

*Description*.— Measurements of largest and smallest specimens are given in Table 2. States of taxonomically important characters are given in Table 3. Dorsal view of body is shown in Fig. 6B; coloration of pterothoracic and abdominal sterna in Fig. 13D; median lobe of male in Fig. 20D; and metacoxal processes in Fig. 22N.

*Taxonomic notes.*— This species appears to be quite distinctive despite the few specimens seen by both Feng and me.

*Variation.*— Too few specimens were seen to establish whether or not there are geographic patterns of variation. No sulcate females were seen but this may be due to the small number of specimens seen.

*Natural history.*— I can find nothing published on the natural history of this species, nor does the scanty label data supply any information.

*Distribution (Fig. 51).*— I have seen specimens from the type locality only. Feng (1937) adds Shensi (=Shanxi Province, China) and Manchuria.

*Chorological relationships.*— Generalizing from the distribution, this species may be sympatric with *D. marginalis czerskii*, *D. delictus*, *D. circumcinctus*, *D. lapponicus*, *D. latro* and possibly *D. latissimus*. The altitude given for the type specimen may indicate an affinity for high altitude habitats, reducing co-occurrence with other species.

*Phylogenetic relationships.*— The species of the *D. dauricus*-group comprise two subgroups. *Dytiscus sinensis* is in the more apotypic of these groups (characterized by the character states discussed under *D. latro*), and within this subgroup shows the highest number of apotypic features.

*Material examined.*— A total of 10 specimens of *D. sinensis* was examined, all from the type locality. Three are males and seven are females.

### Incertae Sedis

One other name is available within *Dytiscus* but for which I am unable to determine a status nor can I assign specimens to this name. Therefore I have left it as *incertae sedis*. A brief statement about this name follows.

*Dytiscus distantus* Feng 1937:14 (Type locality - Manchuria. Type repository listed by Feng (1937:1, 15) as Musée Hoang Ho Pai Ho). Additional locality - Mongolia (T'ang Kia Yingze), June 13, 1927, a male paratype stated as being in the H.T. Feng collection.

Table 2. Range of measurements (mm) of total length (TL), greatest width (GW), and ratio of total length - greatest width (TL/GW) for specimens of each taxon within *Dytiscus* L. (Coleoptera: Dytiscidae). TL/GW not necessarily calculated from TL and GW presented here.

	Total Length	Greatest Width	TL/GW
<i>D. verticalis</i>	29.6 - 36.0	16.5 - 19.4	1.79 - 1.86
<i>D. harrisii</i>	32.4 - 39.0	16.4 - 21.9	1.78 - 1.98
<i>D. hybridus</i>	24.2 - 28.1	12.0 - 14.0	1.90 - 2.02
<i>D. marginicollis</i>	26.7 - 33.0	13.4 - 18.7	1.76 - 2.10
<i>D. habilis</i>	23.0 - 27.5	12.2 - 14.1	1.89 - 1.95
<i>D. semisulcatus</i>	22.8 - 31.6	11.6 - 15.7	1.97 - 2.01
<i>D. sharpi</i>	27.3 - 31.0	14.8 - 16.0	1.84 - 1.94
<i>D. carolinus</i>	22.0 - 26.1	11.8 - 14.0	1.85 - 1.92
<i>D. fasciventris</i>	22.0 - 27.9	11.5 - 15.0	1.80 - 2.10
<i>D. hatchi</i>	22.1 - 28.5	11.7 - 15.6	1.83 - 1.95
<i>D. cordieri</i>	26.3 - 32.5	13.6 - 18.1	1.77 - 2.10
<i>D. mutinensis</i>	28.0 - 31.7	14.0 - 16.0	1.98 - 2.00
<i>D. dimidiatus</i>	29.3 - 39.0	15.9 - 20.0	1.84 - 1.95
<i>D. pisanus</i>	28.0 - 33.9	14.6 - 18.0	1.88 - 1.92
<i>D. m. marginalis</i>	27.6 - 35.2	15.0 - 17.6	1.84 - 2.05
<i>D. m. czerskii</i>	28.7 - 32.6	15.7 - 17.4	1.83 - 1.88
<i>D. persicus</i>	29.3 - 32.4	15.3 - 16.0	1.92 - 2.03
<i>D. delictus</i>	27.5 - 30.6	14.7 - 16.5	1.85 - 1.87

<sup>1</sup> Nearctic specimens.

<sup>2</sup> Palearctic specimens.

Table 3. Character state matrix for taxa included within the genus *Dytiscus* L. (Coleoptera: Dytiscidae). Taxa are scored based on the most common state exhibited by specimens examined. Symbols: m = restricted to males; f = restricted to females; - = character absent from taxon; 1 = character state present; 0 = character state absent. Species names are abbreviated as follows: VERT=*D. verticalis*; HARR=*D. harrisi*; HYBR=*D. hybridus*; MARG=*D. marginicollis*; HABI=*D. habilis*; SEMI=*D. semisulcatus*; SHAR=*D. sharpi*; CARO=*D. carolinus*; FASC=*D. fasciventris*; HATC=*D. hatchi*; CORD=*D. cordieri*; MUTI=*D. mutinensis*; DIMI=*D. dimidiatus*; PISA=*D. pisanus*; MMAR=*D. marginalis*; MCZE=*D. marginalis czerskii*; PERS=*D. persicus*; DELI=*D. delictus*; LATI=*D. latissimus*; CICI=*D. circumcinctus*; ALAS=*D. alaskanus*; DAUR=*D. dauricus*; LLAP=*D. lapponicus lapponicus*; LDIS=*D. lapponicus disjunctus*; CIFL=*D. circumflexus*; THIAN=*D. thianshanicus*; LATR=*D. latro*; and SINE=*D. sinensis*.

## RECONSTRUCTED PHYLOGENY

### Introduction

In this section, I present reasons for regarding the tribe Dytiscini and genus *Dytiscus* as monophyletic. Then, I deal in some detail with the evolution of *Dytiscus*, from a holomorphological point of view.

Methods used for reconstruction of the phylogeny of members of *Dytiscus* are discussed in Ball and Roughley (1982), Roughley and Pengelly (1982) and references cited therein. Also, see the excellent treatment by Ashe (1982:225-229). Characters and character state distribution by taxon are shown in Table 3. The reconstructed phylogeny is shown in Fig. 52. Character state polarity was deduced from ex-group occurrence in members of Dytiscinae. The most easily resolved character consists of two character states found in two groups of taxa. For example, members of Dytiscinae, exclusive of *Dytiscus*, possess rounded metacoxal lobes, whereas members of *Dytiscus* possess either rounded or variously elongated or pointed metacoxal lobes. The unique state expressed only

by some members of *Dytiscus* is therefore considered apotypic for them (Watrous and Wheeler 1981).

Many character states are not discretely distributed, however. Various states of a character can evolve independently by reversal, parallelism, or even convergence (see discussion in Gauld and Mound 1982, and Wiley 1981:12-13, 120-122). Some features of subsets of *Dytiscus* (species-groups, sets of species-groups) were polarized and homoplasies established by means of in-group criteria discussed by de Jong (1980) and Watrous and Wheeler (1981). Most examples of characters of equivocal polarity could be analyzed because of their co-occurrence with more easily established (heavily weighted) character trends (de Jong 1980).

### **Holomorphological Aspects: Dytiscini and *Dytiscus***

*Dytiscini as a monophyletic unit.*— The tribe Dytiscini is comprised of two genera, the dibasic Australian and Tasmanian *Hyderodes* Hope (Watts 1978), and the more diverse Holarctic *Dytiscus*. Sharp (1882:939) was not convinced of the naturalness of this tribe: "... the resemblance or approximation between *Dytiscus* and *Hyderodes* does not arise from genetic connection (or common origin), but is due to a parallelism in the environment of the organisms during their evolution." Sharp does not mention what these environmental similarities might be.

I disagree with Sharp's hypothesis. This is in part based upon characters which Sharp himself has provided (1882:937-939). The first two characters, which I interpret as synapotypic for Dytiscini, is size. The total range of size within the tribe is from 19 to 44 mm, and is not approached by many groups of Hydradephaga except Cybistrini, which range from 13 mm (Brinck 1945) to 47.5 mm (Sharp 1882:713). Large size has evolved independently in members of Dytiscini and Cybistrini.

Sharp (1882:240, 938) discusses the much enlarged spiracular openings of the last two abdominal terga, which are unique to Dytiscini. This character state, then, is also a synapomorphy for the members of the tribe. The enlarged spiracular openings are not due solely to larger size of specimens of Dytiscini as larger members of Cybistrini have relatively smaller openings.

*Dytiscus as a monophyletic unit.*— At least five characters indicate the monophyly of *Dytiscus*. Some of these are more difficult to polarize than others, but in totality they probably indicate the phylogenetic uniqueness of this genus.

1) Large size. Specimens of *Dytiscus* range from 22.6 to 40.0 mm (Table 2) in length, and most are in the range of 24 to 30 mm. Specimens of *Hyderodes* are 19 to 20 mm in length (Sharp 1882:633, 644 and Watts 1978:138; note-- the length of 10.9 mm given by Watts for specimens of *H. crassus* Sharp must be a misprint).

2) Clypeal-frontal suture entire. Sharp (1882:904) mentions that the clypeal suture is complete and distinct throughout its entire length. This is unique among members of the family Dytiscidae, and represents a state similar to that found within at least Hygrobiidae, Amphizoidae, Trachypachidae and Carabidae. Its presence in specimens of *Dytiscus* is interpreted as re-acquisition of this character.

3) Male mesotarsus with very numerous palettes. Male specimens of *Dytiscus* have more than 700 to 1000 palettes per mesotarsal acetabulum. This state is not approached by any other member of Dytiscini that I have examined. For instance, specimens of *Hyderodes* have 18 palettes per mesotarsal

acetabulum. Nevertheless, this character is difficult to polarize. It is unique within Dytiscinae, but is more similar to the state found in many members of Colymbetinae. Relatively numerous palleles probably represent a plesiotypic state (e.g. see discussion in Roughley and Pengelly 1982 for Hydaticini) in certain groups of Dytiscidae, but rarely, if ever, does it approach the numerical abundance found in males of *Dytiscus*. Therefore, I interpret the condition found in the genus as apotypic.

4) Very large spiracular stigma of two apical abdominal terga. Members of Dytiscini are characterized by large stigmata (see above), which in *Dytiscus* are much longer than those of *Hyderodes*.

5) Triangular shape, in cross-section, of apical portion of median lobe. In the discussion of character 7.3 used in the phylogenetic analysis, I characterize the plesiotypic form of the median lobe of male Dytiscinae. Male specimens of *Hyderodes* closely resemble this generalized form. In particular, the apical portion (posterior to flanges) is blade-like, and therefore oval in cross-section. Male specimens of *Dytiscus*, in contrast, have the median lobe more or less widened laterally, and thereby present a triangular cross section of the apical portion.

### Holomorphological Aspects: Evolution of *Dytiscus*

*Characters used in phylogenetic analysis.*— In this section, I list each character in the order in which it appears on Fig. 52, although reference to the characters by numerals is as in Table 3. States of each character are listed along with the suggested transformation series they form, and the basis for this polarity. Character state changes are summarized in Table 7.

**Character A.** Segmentation of labial palpomere I of third-stage larva. Two states: plesiotypic, one-segmented; apotypic, two-segmented. Basis for classification: ex-group.

**Character 3.1.** Explanation of pronotum. Two states: plesiotypic, explanate; apotypic, not explanate. Basis for classification: in-group.

**Character 5.1.** Elytron of female. Two states: plesiotypic, not sulcate, and therefore male-like; apotypic, sulcate. Basis for classification: ex-group.

**Character 7.1.** Lateral ridges of median lobe. Two states: plesiotypic, present; apotypic, absent. Basis for classification: ex-group.

**Character 6.1.** Distribution of palettes on male mesotarsal acetabulum. Two states: plesiotypic, evenly distributed; apotypic, with glabrous area centrally. Basis for classification: ex-group.

**Character 7.5.** Relative length of dorsal and lateral flanges of median lobe of male. Two states: plesiotypic, dorsal equal to, or longer than laterals; apotypic, dorsal much longer than laterals. basis for classification: ex-group and in-group.

**Character 4.6.** Shape of apex of metacoxal process. Four states: plesiotypic, rounded; first apotypic, acute; second apotypic, acuminate; third apotypic, acuminate and elongate. Basis for classification, ex-group and in-group.

**Character 4.7.** Shape of inner margin of metacoxal process. Two states: plesiotypic, convex; apotypic, concave. Basis for classification: ex-group.

**Character 7.3.** Curvature of preapical portion of median lobe of male. Two states: plesiotypic, linear; apotypic, curved. Basis for classification: ex-group.

**Characters 4.1 – 4.5.** Colour of pterothoracic sterna. Three states: plesiotypic, black; first apotypic, black and yellow (fasciate); second apotypic, yellow. Basis for classification: ex-group and in-group.

**Character 7.6.** Roundedness of tip of median lobe of male. Three states: plesiotypic, not rounded; first apotypic, rounded; second apotypic, broadly rounded. Basis for classification: ex-group.

**Character 7.7.** Development of tip of median lobe of male. Two states: plesiotypic, without knob; apotypic, knobbed. Basis for classification: ex-group.

**Character 7.9.** Extension of pre-knob portion of median lobe of male. Two states: plesiotypic, not extended; apotypic, extended. Basis for classification: in-group.

**Character 7.8.** Development of sensory-type pores on tip of median lobe of male. Two states: plesiotypic, absent or, if present, small; apotypic, distinct. Basis for classification: ex-group and in-group.

**Character 7.2.** Curvature of apex of median lobe of male (lateral view). Two states: plesiotypic, straight; apotypic, curved. Basis for classification: ex-group and in-group.

**Character 7.4.** Profile of pre-apical portion of median lobe of male (dorsal view). Two states: plesiotypic, parallel-sided; apotypic, sinuate. Basis for classification: ex-group and in-group.

**Character 7.10.** Relative development of median lobe of male. Two states: plesiotypic, moderate; apotypic, significant. Basis for classification: in-group.

**Character 7.11.** Profile of pre-apical portion of median lobe (dorsal view). Two states: plesiotypic, wider or more robust; apotypic, thinner or less robust. Basis for classification: in-group.

*Characters and homoplasy.*— My interpretation of some characters is not completely apparent from simple description of the characters and their states. The following section explains more fully some characters and justifies my interpretation of others.

**Character A.** Segmentation of labial palpomere I of third-stage larva.

Blunck and Klynstra (1923) discuss the secondary or superimposed segmentation of head appendages of larval stages of species of *Dytiscus*. In the discussion of phylogenetic relationships of *D. verticalis*, the one-segmented labial palpomere I of larvae (Wilson 1923, Fig. 37) was noted to be similar to that of members of *Hyderodes shuckardi* (Watts 1964, Fig. 37). Subsequent study has confirmed the lack of false segmentation of this palpomere in larvae of both of these species.

I have associated adult and third-stage larvae of all Nearctic species except *D. hatchi* (Roughley, unpublished data), and larvae of European species of *Dytiscus* were described by Blunck and Klynstra (1923). Therefore, while known distribution of this character is incomplete (larvae of some eastern Palearctic species of *Dytiscus* are unknown), knowledge is sufficient to suggest use of the derived state as a synapotypy for all species of *Dytiscus* other than *D. verticalis*.

**Character 3.1.** Explanation of pronotum.

Laterally explanate pronota are unique to adult *Dytiscus* among Dytiscinae. As such, this character state is synapotypic for members of *Dytiscus*, though secondarily absent from members of the *D. hybridus*-group. This character is sexually dimorphic in adults of *D. cordieri* (pronotum explanate in females,

only). I deem absence of the explanation in males as a loss of the apotypic condition, and thus an evolutionary reversal.

An alternate phylogeny suggested by the distribution of this character would be one in which the *D. verticalis*- and *D. hybridus*-groups were interchanged in Fig. 52. This would result in explanate pronota representing a synapotypy for all species-groups of *Dytiscus* except the *D. hybridus*-group, rather than for *Dytiscus* as a whole. Also, the derived state of Character A would be unique to a single monobasic species-group (*D. verticalis*). There is little corroborating evidence for either of these hypotheses. I have chosen the representation shown in Figure 52 because specimens of *D. verticalis* exhibit less derived character states than do members of the *D. hybridus*-group, and is thus closer to the hypothetical ancestor of the genus.

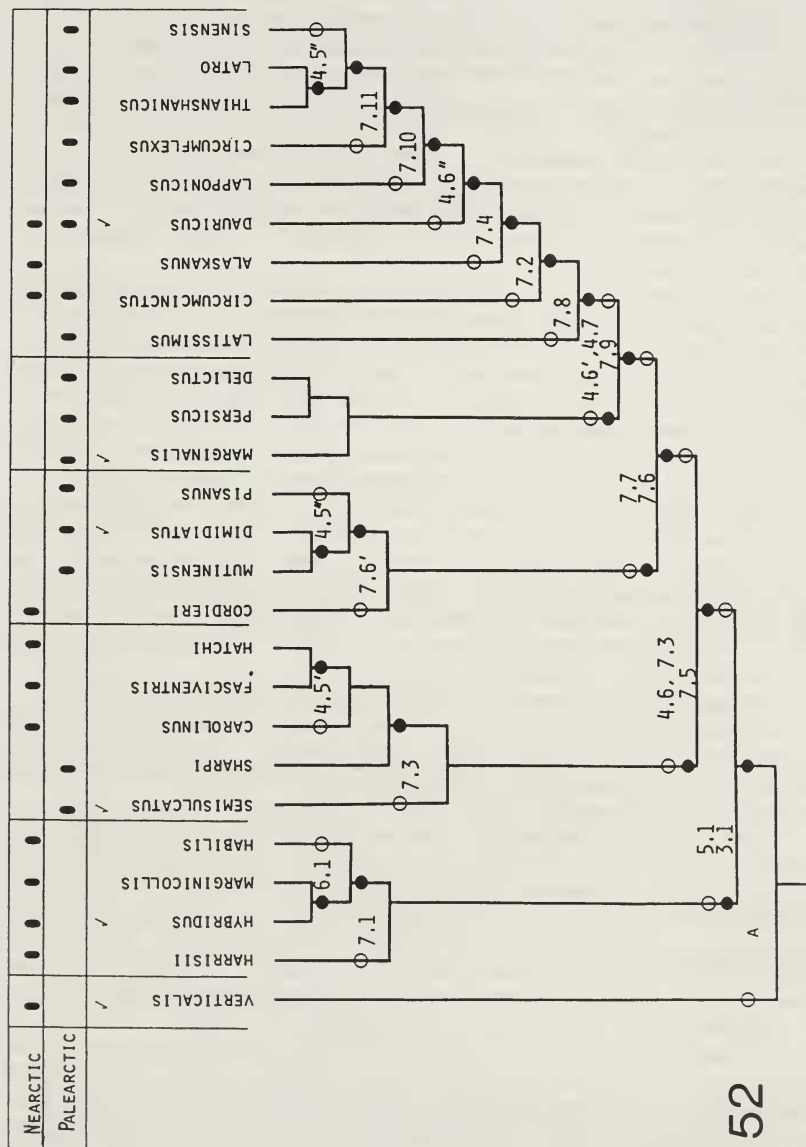

**Character 6.1.** Distribution of palettes on male mesotarsal acetabulum.

In all adult male dytiscines examined, palettes of the mesotarsus are more or less evenly distributed. In specimens of *D. hybridus* and *D. marginicollis*, the acetabulum has a central, longitudinal glabrous area. This is considered an apotypic state. Given that these two members of the *D. hybridus*-group are the only extant species of *Dytiscus* which have such a glabrous area, and that it is achieved in a similar manner, suggests that, even though it is a loss, it is a structural synapotypy for these two taxa. As mentioned under the phylogenetic treatment of *D. hybridus*, this species represents my concept of the hypothetical ancestor of the group, except that it would have had evenly distributed tarsal palettes.

In the absence of this character, I would have rearranged the *D. hybridus*-group, placing *D. hybridus* as the sister group to a lineage including *D. harrisii*, *D. marginicollis* and *D. habilis*. This would have allowed simpler explanation of characters 3.2, 4.2-4.5, 7.1 and 7.5 (see Table 3). The first five of these characters are colour-related, and markedly variable (see Table 7 for Character 4.5). Character 7.2 is discussed elsewhere in this section as being of less phylogenetic weight, and character 7.5 would still require one withinin-species-group reversal for the state found in males of *D. habilis*. The question becomes one of whether or not seven synaptotypes of less weight are more significant than one of more weight. My interpretation demands a negative answer to this question, or demonstration of a single character better than distribution of tarsal palettes. In the absence of the latter, I retain the arrangement shown in Figure 52.

**Character 7.5.** Relative length of dorsal and lateral flanges of median lobe.

Dorsal and lateral flanges of the median lobe are used as guides for the spermatophore during its transfer to, and deposition in, the female's bursa copulatrix (Demandt 1924). In most species of *Dytiscus*, and in species of *Hyderodes*, the two sets of flanges are subequal in length. In some members of both the *D. hybridus*- and *D. semisulcatus*-groups, there is a marked discrepancy in length, presumably brought about by a decrease in length of the lateral flanges. On Figure 52, I have used the apotypic state (dorsal flange longer than lateral flanges) to isolate the *D. semisulcatus*-group. This requires (Table 7) that the apotypic state be derived three times: once in *D. hybridus*, once in *D. habilis*, and once in the common ancestor of the *D. semisulcatus*-group. Furthermore, there is a reversal from the apotypic to the plesiotypic state in one member of the *D. semisulcatus*-group (*D. sharpi*). The alternate arrangement of grouping all species which possess the apotypic state (*D. hybridus*, *D. habilis*, *D. semisulcatus*, *D. carolinus*, *D. fasciventris*, and *D. hatchi*) seems unlikely,

because it would mean that sulcate elytra had evolved more than once (Character 3.1).

**Character 4.6 and 4.7.** Shape of metacoxal process.

The most common form of metacoxal process of members of Dytiscinae is a rounded metacoxal lobe (*i.e.*, not angulate and with inner margin convex). Increasing angle of apex of metacoxal process is a heavily weighted character within my phylogenetic analysis. The three apotypic states represent a transition series easily polarized by comparison to specimens of *Hyderodes* and other Dytiscinae. The second apotypic state is coincident with concave inner margin of the metacoxal process. They are perhaps separate characters, because there is no intermediate character state for shape of the inner margin of the metacoxal process.

Heavy weighting of this character forces recognition of homoplasies in other characters. For example, presence of a knob at the apex of the median lobe of males (Character 7.7) isolates members of the *D. marginalis*- and *D. dauricus*-groups, except for *D. latissimus* and *D. alaskanus* of the latter group. A lesser weight placed on Characters 4.6 and 4.7 would allow these two species to be placed in a separate group as sister lineage to the remainder of the *D. marginalis*-plus *D. dauricus*-groups. This arrangement would suggest that acuminate metacoxal processes with a concave inner margin evolved more than once.

I have chosen to retain Characters 4.6 and 4.7 as heavily weighted because they form a clear morphocline which is easily polarized, and because other arrangements would precipitate recognition of many more homoplasies. For example, the re-arranged phylogeny suggested above would bring about two (as opposed to one) independent developments of the apotypic state of Character 7.8, four (as opposed to three) of Character 7.2, and two each (as opposed to one) of Characters 4.6 and 4.7, discussed above.

**Character 7.3.** Curvature of preapical portion of median lobe of male.

Roughley and Pengelly (1982:280) characterized the plesiotypic dytiscine median lobe as parallel-sided, with unmodified tip. These characters in conjunction with a generally blade-like form of the median lobe comprise the ancestral form of the median lobe of males of Dytiscinae.

Within *Dytiscus*, the apotypic state has evolved at least three times: in *D. hybridus*-group (*D. marginicollis*), in *D. semisulcatus*-group, and is also found in the more advanced species-groups, but lost in *D. pisanus*. The sporadic parallelisms and the reversal of the apotypic state of this character are perhaps not surprising when it is considered that the change is simple and probably easily achieved in the evolution of various lineages. It is therefore to be considered a character of low importance for reconstruction of phylogeny.

**Characters 4.1 - 4.5.** Colour of pterothoracic sterna.

Ventral colouration among species of *Dytiscus* is variable within species as well as within species-groups, and both apotypic states have occurred independently in a number of lineages. Among members of *Dytiscus*, however, there is a generalized group trend from darker to lighter in all colour-related characters (2.1, 3.2, 3.3, 4.1-4.5: see Table 3). All are characters of low phylogenetic weight and they are highly variable (Table 7).

**Character 7.7.** Development of tip of median lobe of male.

The generalized ex-group form of the median lobe of dytiscines is discussed under the treatment of Character 7.3. The derived state of this character unites the *D. marginalis*- and *D. dauricus*-groups. Within the latter, absence of the apotypic state from male specimens of *D. latissimus* and *D. alaskanus* represent secondary, independent losses, as discussed under Characters 4.6 and 4.7, above.

Table 7. Number of changes of state (derivation of apotypic state or reversal to plesiotypic state) for the 19 characters used for phylogenetic reconstruction of the genus *Dytiscus* L. (Coleoptera: Dytiscidae). All characters are scored as if existing in two states only. Based on Table 3 and Figure 52.

Total number of characters undergoing given number of state changes.	8	3	2	4	1	1

Total number state changes = 47.

**Character 7.9.** Extension of pre-knob portion of median lobe of male.

The apotypic condition as represented by members of the *D. marginalis*-group consists of a narrowing and elongation of the pre-apical portion just before the apical knob. The apotypic condition of this character is distinct from that of Character 7.11, discussed below, in which the entire pre-apical portion is narrowed.

**Character 7.2.** Curvature of apex of median lobe of male (lateral view).

The primitive form of the median lobe is discussed under the treatment of Character 7.3. Subsequent modification of this basic plan has occurred many times in the history of the subfamily (group trend, e.g. see Roughley and

Pengelly 1982). Within *Dytiscus*, there is evidence of the plesiotypic state of this character in the plesiotypic members of two lineages (*D. verticalis* and *D. harrisii*) and of three independent derivations of the apotypic state (*D. sharpi*, *D. pisanus*, and all but two members of the *D. dauricus*-group). This character is similar to Character 7.3 in that conversion to the apotypic state probably is accomplished easily and thus is considered to be of low phylogenetic weight.

**Character 7.10.** Relative development of knob of median lobe of male (dorsal view).

The apotypic state of this character is relative and subjective. However, the distinctiveness of the change is apparent. The apotypic state of this character would be coincident with that of Character 7.11 if it were not for *D. circumflexus*, males of which have a very distinctive apical knob, but the apex is not excessively narrowed.

*Evolution of genitalia of males of Dytiscus.*— I have assigned form of the median lobe of male genitalia some importance for both recognition of species level status and for phylogenetic analysis. The male genitalia are much more than simply a set of characters, and must be treated as a functional evolutionary unit. Therefore, the purpose of this section is to trace the history of male genitalia as detailed by the reconstructed phylogeny proposed (Figure 52). My method has involved description of a hypothetical type of genitalia, to which are assigned the characteristics I believe to be primitive, and then to discuss the form and modification of the median lobe from primitive through derived species-groups.

Ancestral dytiscines probably possessed a J-shaped median lobe with a longer portion, or shaft, parallel-sided, with an unmodified, straight, blade-like tip (based in part on Roughley and Pengelly 1982:280). Located dorsally on the median lobe are two lateral and one dorsal flange, which form a guide, or channel, for the spermatophore during copulation (Demandt 1924). This form of median lobe, except for the straight tip, is seen in extant *Prodaticus*, a basal hydaticine, and *Hyderodes*, a basal dytiscine.

Coincident with the origin of the genus *Dytiscus* was derivation of a median lobe with a triangular cross section. The plesiotypic, blade-like condition was modified by lateral extension of the sides and perhaps also by strengthening of the ventral ridge. These steps have created the triangular form of the apex. The form of the median lobe closest to this ancestral type within *Dytiscus* is seen in specimens of *D. verticalis* (Fig. 14A), and *D. harrisii* (Fig. 14B).

Earlier, I discussed the form of the apex of the median lobe as the major taxonomic criterion for delimiting species level taxa, and noted the uniformity of this character within species. This implies selection for uniformity within species, and that difference in form of the apex of the median lobe could be an isolating mechanism for species. This latter point is exemplified by members of the *D. hybridus*-group (Figs. 14B-D, 15A). As recorded above, *D. harrisii* (Fig. 14B) has the plesiotypic form within the group. The median lobe of *D. marginicollis* (Fig. 14D) is similar to that of *D. harrisii* except that the tip is abruptly deflexed. The allopatric *D. hybridus* (Fig. 14C) and *D. habilis* (Fig. 15A) have shortened lateral flanges, lack distinct lateral ridges, and have slightly (*D. hybridus*) or more prominently (*D. habilis*) modified tips. In addition, the pre-apical portion of the median lobe of *D. hybridus* is slender, whereas it is greatly thickened in male *D. habilis*. In summary, modification of five characteristics within three species has produced four markedly different forms of the median lobe.

Within the *D. semisulcatus*-group (Figs. 15B-D, 16A-B), the nominate species (Fig. 15B) has the median lobe similar to that of the plesiotypic form but less triangular and with the dorsal flange markedly elongate. An elongate dorsal flange is characteristic of three other species of the group (*D. sharpi* [Fig. 15C] is the exception). All but the nominate species have the tip abruptly deflexed, although it is more deflexed in *D. sharpi* than in the others, and males of this taxon also have the tip modified. The median lobe of *D. carolinus* (Fig. 15D) and *D. hatchi* (Fig. 16B) lack any remnant of a lateral ridge, whereas that of *D. fasciventris* exhibits it, although only apically. Conversely, the median lobe of males of *D. carolinus* and *D. fasciventris* (Fig. 16A) share a curious subapical depression in dorsal view.

It is interesting that the members of this group are largely allopatric and yet show a high degree of divergence in the form of the median lobe and that the three Nearctic species (*D. carolinus*, *D. fasciventris* and *D. hatchi*) have the most similar form of the median lobe. The former is probably the result of the long isolation of the species of this group, and the latter to more recent speciation among them than between them and the other members of the clade. Members of this group exhibit modifications in the same five characteristics found in the *D. hybridus*-group, but show more stages of some of these (*i.e.*, deflection of the tip, reduction of lateral flanges, and effacement of the lateral ridge) and added another characteristic (dorsal depression).

The *D. dimidiatus*-group is characterized by a rounded tip of the median lobe (Figs. 16C-D, 17A-B). All have the apex deflexed, and all but the Nearctic *D. cordieri* (Fig. 16C) have the tip quite broadly rounded, with distinct lateral ridges. Specimens of *D. cordieri* exhibit some characters of the plesiotypic form except those noted above, and the swollen area above the place the lateral ridges would normally be located. Specimens of the Palearctic species *D. mutinensis* (Fig. 16D) and *D. dimidiatus* (Fig. 17A) are very similar in form and, as argued in the text, this is perhaps best considered as an example of recent speciation. Co-occurring geographically with these latter two species is *D. pisanus* (Fig. 17B) of which the apical portion of the median lobe has a host of unique characteristics, such as very broad tip, sinuate lateral margin (in lateral view), and great development of ventral setation towards the apex. Members of the *D. dimidiatus*-group thus show, in form and subsequent modification of the median lobe, few similarities to the previously discussed species-groups of *Dytiscus*.

Both the *D. marginalis*- and *D. dauricus*-groups are characterized by presence of a distinct knob on the median lobe (secondarily lost from males of *D. alaskanus* (Fig. 19B) and *D. latissimus* (Fig. 18C) of the latter species-group). The *D. marginalis*-group (Figs. 17C-D, 18A-B) is unique because of the extension of the pre-apical knob portion (Character 7.9). All species have subequal flanges, distinct lateral ridges, and a general similarity in form. There are minor differences in shape of the knob when seen in ventral view, and the relative thickening of the ventral ridge. All of the four forms included in this group occur exclusively in the Palearctic region. Of these only *D. marginalis cerskii* and *D. delictus* are broadly sympatric. In the latter (Fig. 18B), the apex of the median lobe is stouter and the distance from the tip to the dorsal flange is appreciably shorter. Therefore, in this group of species, the integrity of taxa is perhaps more sustained by allopatry and other differences in life history than by divergence in form of the median lobe.

As mentioned previously, two members of the *D. dauricus*-group (Figs. 18C-D, 19A-D, 20A-D) have lost the apical knob of the median lobe, yet the median lobe of both species remains qualitatively different. All species have deflexed

apices, distinct lateral ridges and subequal dorsal flanges. The apical portion of the median lobe is flatly arched in *D. circumcinctus* (using the lateral ridges as a reference point, Fig. 19A), and more abruptly arched in more advanced species (except *D. alaskanus*, Fig. 19B), which also have sinuate lateral margins (in dorsal view). Members of *D. circumcinctus* and all other advanced species have well-developed sensory-type pores on the apical knob (Fig. 19E). Their function is unknown to me. Males of *D. circumcinctus* (Fig. 19A), *D. thianshanicus* (Fig. 20B), *D. latro* (Fig. 20C) and *D. sinensis* (Fig. 20D) possess quite a prominent knob at the apex, and the latter three taxa have a distinctly thinner pre-apical portion (in dorsal view) which produces an even greater prominence of the apical knob.

As in the *D. marginalis*-group, the degree of differentiation among species based on the form of the apex of the median lobe is less dramatic within the *D. dauricus*-group than in the *D. hybridus*- and *D. semisulcatus*-groups. However, within the *D. dauricus*-group, unlike the *D. marginalis*-group, many of species of the former occur sympatrically. This could be interpreted as reflecting less reliance on the median lobe as an isolating mechanism, although the fact that each form of apex is distinctive somewhat negates this. It seems more reasonable to suggest that at least some members of the *D. dauricus*-group have arisen more recently than have species of some other groups, and therefore have had less time available for divergence. Other isolating factors associated with life history could be operating to augment the mechanical isolation supplied by genital differences.

Of the six species-groups recognized within *Dytiscus*, members of two (*D. verticalis*- and *D. hybridus*-groups) have a median lobe which appears quite similar to that reconstructed for the hypothetical ancestor of the genus. Plesiotypic members of the *D. semisulcatus*- and *D. dimidiatus*-groups show some but not extreme modification from the ancestral type. In the *D. marginalis*- and *D. dauricus*-groups, the common presence of an apical knob places them as quite derived from the ancestral type.

Parallel, dramatic changes in form of the apex of the median lobe characterize species in the *D. hybridus*- and *D. semisulcatus*-groups. A high degree of differentiation is found in members of the *D. dimidiatus*-group as well. The *D. marginalis*- and *D. dauricus*-groups show comparatively less within-group differentiation, and yet the presence of the apical knob is certainly a strong isolating mechanism between these two groups and the four more plesiotypic groups.

In summary, there is a transformation series shown by the species-groups of *Dytiscus* in the form of the apex of the median lobe. The series is disguised by within-group changes, and is apparent only after examination of the plesiotypic forms within each species-group. (That the plesiotypic member of each group exhibits a form of median lobe most similar to a hypothetical ancestor of that group probably reflects heavy emphasis on the median lobe for construction of the proposed phylogeny, within species-groups, in the first place! The same is not true, however, for comparisons between groups, where, as mentioned elsewhere, other characters such as form of the metacoxal processes were more heavily weighted).

## CONCLUDING STATEMENT

The classification of species of *Dytiscus* is far from complete. Many type specimens of junior synonyms remain to be studied; of some 75 names treated herein type material has been studied recently of only 26. Further study will undoubtedly bring about re-assignment of some of these names (e.g. see discussion of *D. fuscostriatus* within the treatment of *D. circumcinctus*). Similarly types of the following senior names need to be carefully studied (if indeed they still exist): *D. carolinus* Aubé, *D. circumcinctus* Ahrens, *D. circumflexus* Fabricius, *D. cordieri* Aubé, *D. czerskii* Zaitsev, *D. delictus* Zaitsev, *D. dimidiatus* Bergsträsser, *D. distantus* Feng, *D. fasciventris* Say, *D. habilis* Say, *D. hybridus* Aubé, *D. lapponicus* Gyllenhal, *D. latissimus* Linnaeus, *D. marginalis* Linnaeus, *D. semisulcatus* Müller and *D. verticalis* Say. Therefore while some changes in nomenclature are to be expected I believe these are minor and that the overall classification is sound.

As mentioned elsewhere my studies of *Dytiscus* are not complete yet. Further analysis will be presented through study of immature stages and of zoogeography and reconstructed phylogeny. After that an advanced level of understanding of the systematics of *Dytiscus* will have been achieved. It is hoped that this understanding will provide the framework for further studies of other topics using *Dytiscus*. For instance, in terms of ecological studies there is a very unequal coverage. In the Palearctic realm, *D. marginalis* is well studied whereas in the Nearctic region the best studied species is *D. alaskanus* yet even casual comparison of the literature about these two species shows that the former is much better known than is the latter. Many interesting questions about the natural history of *Dytiscus* are yet to be resolved. For instance some but not all species are specialized predators of immature aquatic vertebrates (e.g. salamanders, frogs and fish) or of immature aquatic invertebrates (e.g. caddisflies) whereas other species appear to be predators of anything that they can overpower. How widespread is specialized predation and how did it evolve?

One feature of specimens of *Dytiscus* which makes them very suitable for further research is their large size. Their size renders them suitable for most kinds of studies carried out by entomologists. For instance, they are easy animals to observe, particularly when maintained in aquaria, and therefore study of their behaviour may yield interesting data.

One of the many fascinating evolutionary problems that remains unsolved is the purpose and function of the sulcate grooves of some females of *Dytiscus*. A variety of theories have been put forward to explain their existence but none of these stands up to critical analysis. Most species of *Dytiscus* are known to possess sulcate elytra; in only few species were all females sulcate, in other species sulcate females predominate in the southern portion of the geographic range whereas in other species the reverse is true. If these sulcae have an important role then why are they found only in females, what are the mechanisms by which sulcae are lost, etc.?

Considering that the classification of *Dytiscus* is relatively stabilized this should open the door for further study of many interesting and unique phenomena of these animals.

## ACKNOWLEDGEMENTS

I express appreciation to my supervisor, G.E. Ball for his help and advice during my study. His constant enthusiasm and insight as well as his attitude

toward teaching and research were of great value. The climate of learning which he has helped create in the Department of Entomology of the University of Alberta made the opportunity to study and conduct research there a very beneficial experience.

D.A. Craig, B.S. Heming, C. Schweger, J.R. Spence and H.B. Leech assisted by serving on my committee, by reading the thesis on which this paper was based, and in many other ways. E. Maw has assisted with some of the technical aspects of manuscript production, particularly during the early stages; D. Holder, D.A. Pollock and I.S. Askevold also assisted me in Winnipeg.

S. Wroot worked very efficiently and quickly to provide the habitus drawings; her effort and skill are greatly appreciated. G.D. Braybrook provided technical assistance with scanning electron microscope work. J.S. Scott provided valuable technical advice concerning arrangement and methods of presentation of the plates. M.G. McIntyre assisted in designing and building a mechanical microscope stage for measuring specimens and provided other technical expertise. F.A.H. Sperling and I.S. Askevold assisted with, or checked the accuracy of German translations, and J.F. and M. Landry provided similar help with French translations; G. Léger (Winnipeg) also assisted with French translations and with typing and computer formatting.

I express appreciation to the librarians in charge of the Inter-Library loans office both at the University of Manitoba and at the University of Alberta for their assistance in tracking down some of the more obscure literature sources. In this regard I owe a great debt to the librarians at the British Museum (Natural History) for their courtesy, helpfulness and efficiency during my visits to that institution.

To my former colleagues in the Department of Entomology, University of Alberta, I owe a great deal. They were most helpful in discussions of specific problems and of general theory and application of systematics, as well as providing many specimens of *Dytiscus* or other information. I thank them all, but certain of them deserve special mention for their detailed contributions. These are R.B. Aiken, J.S. Ashe, A. Borkent, H. Goulet, D. Kavanaugh, D. Lafontaine, F. Leggett, A.P. Nimmo and J.R. Spence, as well as J. Acorn, R.S. Anderson, J. Cumming, D.C. Currie, H. Frania, G.A.P. Gibson, J.F. Landry, E. Maw, J. O'Hara, K. Shaw and F.A.H. Sperling. Also, I greatly appreciate the assistance and enthusiasm of many colleagues from other institutions who assisted with obtaining obscure literature, specimens, *etc.* D. Larson (St. John's) and A. Nilsson (Umeå) provided vigorous and effective reviews of this manuscript.

As explained elsewhere, examination of specimens of *Dytiscus* involved visiting collections, and I express my appreciation to the respective curators for their assistance during my visit to their institutions. In particular, M.E. Bacchus and P.M. Hammond at BM(NH) and, J.J. Menier (MNHN) provided a good deal of assistance with types in their collections.

Travel, field work and other financial support was provided by NSERC Canada grant #A-1399 held by G.E. Ball. Field work in Yukon Territory in 1977 was supported by a grant to the Beringea Yukon Refugium Project administered by J.V. Matthews, Jr., Geological Survey of Canada, Ottawa. Field work in the eastern arctic of Canada during 1979 was supported by the Boreal Institute, University of Alberta. Subsequent research and museum travel and publication costs were supported by NSERC Canada grant #A0428 to RER.

I acknowledge also the forbearance and assistance of the faculty and staff of the Department of Entomology, University of Manitoba, during my dual status as student and faculty member.

Last, but foremost, was the support, help and enthusiasm of my wife Marsha. I am fortunate to share my life with a person who both understands and participates in my work.

# INDEX TO NAMES OF TAXA

(Junior synonyms in *italics*)

## FAMILY GROUP TAXA

Colymbetinae 524  
 Cybistrini 523  
 Dytiscidae 524  
 Dytiscinae 522, 524, 525, 528  
 Dytiscini 523  
 Hydaticini 524  
 Hydradephaga 383, 523

## GENERA AND SUBGENERA

*Dyticopsis* Houlbert 399  
*Dytiscus* Müller 382, 398  
*Dytiscus* Linnaeus 382–383, 387,  
 393, 398, 400,  
 431, 455, 522–525, 530  
*Hyderodes* Hope 400, 523, 528,  
 530  
*Leionotus* Kirby 399  
*Macrodytes* Thomson 398, 474  
*Prodaticus* 530

## SPECIES AND SUBSPECIES

*alaskanus* J. Balfour-Browne,  
*Dytiscus* 401, 403,  
 431, 454, 455, 475, 479, 480–  
 483, 531  
*albionicus* Motschulsky, *Dytiscus*  
 403, 434, 476  
*amplissimus* Müller, *Dytiscus* 474  
*amurensis* J. Balfour-Browne,  
*Dytiscus* 482  
*anastomozans* Well, *Dytiscus* 474  
*angustatus* Stepenes, *Dytiscus*  
 475, 476  
*anxius* Mannerheim, *Dytiscus* 438,  
 475  
*carolinus* Aubé, *Dytiscus* 397,  
 401–402, 435, 445,  
 481, 526, 531  
*circumcinctus* Ahrens, *Dytiscus*  
 394, 396, 401, 429, 432, 434,  
 454, 468–469, 475–480, 486,  
 492, 494, 532  
*circumcinctus flavocinctus*  
 Hummel, *Dytiscus* 475  
*circumcinctus striatus* Bruce,  
*Dytiscus* 475  
*circumductus* Serville, *Dytiscus*  
 398, 466

*circumflexus dubius* Serville,  
*Dytiscus* 489  
*circumflexus* Fabricius, *Dytiscus*  
 401, 429, 469, 475, 484, 488,  
 489, 490, 491, 493  
*circumscriptus* Boisduval and  
 Lacordaire, *Dytiscus* 475  
*compar* Melsheimer, *Leionotus* 432  
*confluens* Say, *Dytiscus* 435, 481  
*conformis* Kunze, *Dytiscus* 395,  
 399, 466, 481  
*confusus* Motschulsky, *Dytiscus*  
 403, 475, 476  
*cordieri* Aubé, *Dytiscus* 394, 396,  
 401, 402, 454,  
 455, 457, 525, 531  
*crassus* Sharp, *Hyderodes* 523  
*czerskii* Zaitsev, *Dytiscus* 467  
*dauricus* Gebler, *Dytiscus* 388, 396,  
 397, 401, 431, 435, 444, 469,  
 475, 476, 479, 481, 482, 483,  
 484, 486, 492  
*dauricus obscurus* Gschwendtner,  
*Dytiscus* 482  
*delictus* (Zaitzev), *Dytiscus* 397,  
 401, 427, 444,  
 469, 475, 486, 493, 494, 531  
*delictus* Zaitzev, *Macrodytes* 469  
*dimidiatus* Bergsträsser, *Dytiscus*  
 401, 427, 456–457, 469, 475,  
 482, 491, 531  
*dimidiatus mutinensis* Fiori,  
*Dytiscus* 456, 458  
*disjunctus* Camerano, *Dytiscus*  
 485–6  
*distantus* Feng, *Dytiscus* 506  
*dubius* Gyllenhal, *Dytiscus* 475  
*dubius* Serville, *Dytiscus* 399, 489  
*excrucians* Stephens, *Dytiscus* 489  
*fasciventris* Say, *Dytiscus* 394,  
 401–402, 444–447, 454, 526,  
 531  
*flavocinctus* Hummel, *Dytiscus* 475  
*flavomaculatus* Curtis, *Dytiscus*  
 489  
*flavoscutellatus* Latreille, *Dytiscus*  
 489  
*franklinii* Kirby, *Dytiscus* 427  
*frischi* Bergsträsser, *Dytiscus* 442
